1 Abstract

2 Accurate assessment of anthropogenic carbon dioxide (CO_2) emissions and their redistribution
3 among the atmosphere, ocean, and terrestrial biosphere – the ‘global carbon budget’ – is
4 important to better understand the global carbon cycle, support the development of climate
5 policies, and project future climate change. Here we describe data sets and methodology to
6 quantify the five major components of the global carbon budget and their uncertainties. CO_2
7 emissions from fossil fuels and industry (E_{FF}) are based on energy statistics and cement production
8 data, respectively, while emissions from land-use change (E_{LUC}), mainly deforestation, are based
9 on land-cover change data and bookkeeping models. The global atmospheric CO_2 concentration is
10 measured directly and its rate of growth (G_{ATM}) is computed from the annual changes in
11 concentration. The ocean CO_2 sink (S_{OCEAN}) and terrestrial CO_2 sink (S_{LAND}) are estimated with
12 global process models constrained by observations. The resulting carbon budget imbalance (B_{IM}),
13 the difference between the estimated total emissions and the estimated changes in the
14 atmosphere, ocean, and terrestrial biosphere, is a measure of our imperfect data and
15 understanding of the contemporary carbon cycle. All uncertainties are reported as $\pm 1\sigma$. For the
16 last decade available (2007–2016), E_{FF} was $9.4 \pm 0.5 \text{ GtC yr}^{-1}$, E_{LUC} $1.3 \pm 0.7 \text{ GtC yr}^{-1}$, G_{ATM} 4.7 ± 0.1
17 GtC yr^{-1} , S_{OCEAN} $2.4 \pm 0.5 \text{ GtC yr}^{-1}$, and S_{LAND} $3.0 \pm 0.8 \text{ GtC yr}^{-1}$, with a budget imbalance B_{IM} of 0.6
18 GtC yr^{-1} indicating overestimated emissions and/or underestimated sinks. For year 2016 alone, the
19 growth in E_{FF} was approximately zero and emissions remained at $9.9 \pm 0.5 \text{ GtC yr}^{-1}$. Also for 2016,
20 E_{LUC} was $1.3 \pm 0.7 \text{ GtC yr}^{-1}$, G_{ATM} was $6.1 \pm 0.2 \text{ GtC yr}^{-1}$, S_{OCEAN} was $2.6 \pm 0.5 \text{ GtC yr}^{-1}$ and S_{LAND} was
21 $2.7 \pm 1.0 \text{ GtC yr}^{-1}$, with a small B_{IM} of -0.3 GtC . G_{ATM} continued to be higher in 2016 compared to
22 the past decade (2007–2016), reflecting in part the higher fossil emissions and smaller S_{LAND} for
23 that year consistent with El Niño conditions. The global atmospheric CO_2 concentration reached
24 $402.8 \pm 0.1 \text{ ppm}$ averaged over 2016. For 2017, preliminary data indicate a renewed growth in E_{FF}
25 of +2.0% (range of 0.8% to 3.0%) based on national emissions projections for China, USA, and
26 India, and projections of Gross Domestic Product corrected for recent changes in the carbon
27 intensity of the economy for the rest of the world. For 2017, initial data indicate an increase in
28 atmospheric CO_2 concentration of around 5.3 GtC (2.5 ppm), attributed to a combination of
29 increasing emissions and receding El Niño conditions. This living data update documents changes
30 in the methods and data sets used in this new global carbon budget compared with previous
31 publications of this data set (Le Quéré et al., 2016; 2015b; 2015a; 2014; 2013). All results
32 presented here can be downloaded from <https://doi.org/10.18160/GCP-2017>.

1 **1 Introduction**

2 The concentration of carbon dioxide (CO₂) in the atmosphere has increased from approximately
3 277 parts per million (ppm) in 1750 (Joos and Spahni, 2008), the beginning of the Industrial Era, to
4 402.8 ± 0.1 ppm in 2016 (Dlugokencky and Tans, 2016; Fig. 1). The atmospheric CO₂ increase
5 above preindustrial levels was, initially, primarily caused by the release of carbon to the
6 atmosphere from deforestation and other land-use change activities (Ciais et al., 2013). While
7 emissions from fossil fuels started before the Industrial Era, they only became the dominant
8 source of anthropogenic emissions to the atmosphere from around 1920 and their relative share
9 has continued to increase until present. Anthropogenic emissions occur on top of an active natural
10 carbon cycle that circulates carbon between the reservoirs of the atmosphere, ocean, and
11 terrestrial biosphere on time scales from sub-daily to millennia, while exchanges with geologic
12 reservoirs occur at longer timescales (Archer et al., 2009).

13 The global carbon budget presented here refers to the mean, variations, and trends in the
14 perturbation of CO₂ in the atmosphere, referenced to the beginning of the Industrial Era. It
15 quantifies the input of CO₂ to the atmosphere by emissions from human activities, the growth rate
16 of atmospheric CO₂ concentration, and the resulting changes in the storage of carbon in the land
17 and ocean reservoirs in response to increasing atmospheric CO₂ levels, climate change and
18 variability, and other anthropogenic and natural changes (Fig. 2). An understanding of this
19 perturbation budget over time and the underlying variability and trends of the natural carbon
20 cycle are necessary to understand the response of natural sinks to changes in climate, CO₂ and
21 land-use change drivers, and the permissible emissions for a given climate stabilization target.

22 The components of the CO₂ budget that are reported annually in this paper include separate
23 estimates for the CO₂ emissions from (1) fossil fuel combustion and oxidation and cement
24 production (E_{FF} ; GtC yr⁻¹) and (2) the emissions resulting from deliberate human activities on land
25 leading to land-use change (E_{LUC} ; GtC yr⁻¹); and their partitioning among (3) the growth rate of
26 atmospheric CO₂ concentration (G_{ATM} ; GtC yr⁻¹), and the uptake of CO₂ (the 'CO₂ sinks') in (4) the
27 ocean (S_{OCEAN} ; GtC yr⁻¹) and (5) on land (S_{LAND} ; GtC yr⁻¹). The CO₂ sinks as defined here conceptually
28 include the response of the land (including inland waters and estuaries) and ocean (including
29 coasts and seaward edge) to elevated CO₂ and changes in climate, rivers, and other environmental
30 conditions, although in practice not all processes are accounted for (see Section 2.7). The global
31 emissions and their partitioning among the atmosphere, ocean and land are in reality in balance,

1 however due to imperfect spatial and/or temporal data coverage, errors in each estimate and due
2 to smaller terms not included in our budget estimate (discussed in Section 2.7), their sum does
3 not necessarily add up to zero. We introduce here a budget imbalance (B_{IM}), which is a measure of
4 the mismatch between the estimated emissions and the estimated changes in the atmosphere,
5 land and ocean. This is an important change in the calculation of the global carbon budget. With
6 this change, the full global carbon budget now reads:

$$E_{FF} + E_{LUC} = G_{ATM} + S_{OCEAN} + S_{LAND} + B_{IM}. \quad (1)$$

7 G_{ATM} is usually reported in ppm yr^{-1} , which we convert to units of carbon mass per year, GtC yr^{-1} ,
8 using $1 \text{ ppm} = 2.12 \text{ GtC}$ (Table 1). We also include a quantification of E_{FF} by country, computed
9 with both territorial and consumption based accounting (see Sect. 2). Equation (1) partly omits the
10 net input of CO_2 to the atmosphere from the chemical oxidation of reactive carbon-containing
11 gases from sources other than the combustion of fossil fuels (discussed in Sect. 2.7).

12 The CO_2 budget has been assessed by the Intergovernmental Panel on Climate Change (IPCC) in all
13 assessment reports (Ciais et al., 2013; Denman et al., 2007; Prentice et al., 2001; Schimel et al.,
14 1995; Watson et al., 1990), and by others (e.g. Ballantyne et al., 2012). The IPCC methodology has
15 been adapted and used by the Global Carbon Project (GCP, www.globalcarbonproject.org), which
16 has coordinated a cooperative community effort for the annual publication of global carbon
17 budgets up to year 2005 (Raupach et al., 2007; including fossil emissions only), year 2006
18 (Canadell et al., 2007), year 2007 (published online; GCP, 2007), year 2008 (Le Quéré et al., 2009),
19 year 2009 (Friedlingstein et al., 2010), year 2010 (Peters et al., 2012b), year 2012 (Le Quéré et al.,
20 2013; Peters et al., 2013), year 2013 (Le Quéré et al., 2014), year 2014 (Friedlingstein et al., 2014;
21 Le Quéré et al., 2015b), year 2015 (Jackson et al., 2016; Le Quéré et al., 2015a), and most recently
22 year 2016 (Le Quéré et al., 2016). Each of these papers updated previous estimates with the latest
23 available information for the entire time series.

24 We adopt a range of ± 1 standard deviation (σ) to report the uncertainties in our estimates,
25 representing a likelihood of 68% that the true value will be within the provided range if the errors
26 have a Gaussian distribution. This choice reflects the difficulty of characterising the uncertainty in
27 the CO_2 fluxes between the atmosphere and the ocean and land reservoirs individually,
28 particularly on an annual basis, as well as the difficulty of updating the CO_2 emissions from land-
29 use change. A likelihood of 68% provides an indication of our current capability to quantify each
30 term and its uncertainty given the available information. For comparison, the Fifth Assessment

1 Report of the IPCC (AR5) generally reported a likelihood of 90% for large data sets whose
2 uncertainty is well characterised, or for long time intervals less affected by year-to-year variability.
3 Our 68% uncertainty value is near the 66% which the IPCC characterises as ‘likely’ for values falling
4 into the $\pm 1\sigma$ interval. The uncertainties reported here combine statistical analysis of the
5 underlying data and expert judgement of the likelihood of results lying outside this range. The
6 limitations of current information are discussed in the paper and have been examined in detail
7 elsewhere (Ballantyne et al., 2015; Zscheischler et al., 2017).

8 All quantities are presented in units of gigatonnes of carbon (GtC, 10^{15} gC), which is the same as
9 petagrams of carbon (PgC; Table 1). Units of gigatonnes of CO_2 (or billion tonnes of CO_2) used in
10 policy are equal to 3.664 multiplied by the value in units of GtC.

11 This paper provides a detailed description of the data sets and methodology used to compute the
12 global carbon budget estimates for the period preindustrial (1750) to 2016 and in more detail for
13 the period 1959 to 2016. We also provide decadal averages starting in 1960 including the last
14 decade (2007-2016), results for the year 2016, and a projection for year 2017. Finally we provide
15 cumulative emissions from fossil fuels and land-use change since year 1750, the preindustrial
16 period, and since year 1870, the reference year for the cumulative carbon estimate used by the
17 IPCC (AR5) based on the availability of global temperature data (Stocker et al., 2013). This paper is
18 updated every year using the format of ‘living data’ to keep a record of budget versions and the
19 changes in new data, revision of data, and changes in methodology that lead to changes in
20 estimates of the carbon budget. Additional materials associated with the release of each new
21 version will be posted at the Global Carbon Project (GCP) website
22 (<http://www.globalcarbonproject.org/carbonbudget>), with fossil fuel emissions also available
23 through the Global Carbon Atlas (<http://www.globalcarbonatlas.org>). With this approach, we aim
24 to provide the highest transparency and traceability in the reporting of CO_2 , the key driver of
25 climate change.

26 **2 Methods**

27 Multiple organizations and research groups around the world generated the original
28 measurements and data used to complete the global carbon budget. The effort presented here is
29 thus mainly one of synthesis, where results from individual groups are collated, analysed and
30 evaluated for consistency. We facilitate access to original data with the understanding that

1 primary data sets will be referenced in future work (See Table 2 for ‘How to cite’ the data sets).
 2 Descriptions of the measurements, models, and methodologies follow below and in depth
 3 descriptions of each component are described elsewhere.
 4 This is the 12th version of the global carbon budget and the sixth revised version in the format of a
 5 living data update. It builds on the latest published global carbon budget of Le Quéré et al. (2016).
 6 The main changes are: (1) the inclusion of data to year 2016 (inclusive) and a projection for the
 7 global carbon budget for year 2017; (2) the use of two bookkeeping models to assess E_{LUC} (instead
 8 of one), (3) the use of Dynamic Global Vegetation Models (DGVMs) to assess S_{LAND} , (4) the
 9 introduction of the budget imbalance B_{IM} as the difference between the estimated emissions and
 10 sinks, thus removing the assumption in previous global carbon budgets that the main
 11 uncertainties are primarily on the land sink (S_{LAND}), and recognising uncertainties in the estimate
 12 of S_{OCEAN} , particularly on decadal time-scales, (5) the addition of a table presenting the major
 13 known sources of uncertainties, and (6) the expansion of the model descriptions. The main
 14 methodological differences between annual carbon budgets are summarised in Table 3.

15 **2.1 CO₂ emissions from fossil fuels and industry (E_{FF})**

16 **2.1.1 Emissions estimates**

17 The estimates of global and national CO₂ emissions from fossil fuels, including gas flaring and
 18 cement production (E_{FF}), relies primarily on energy consumption data, specifically data on
 19 hydrocarbon fuels, collated and archived by several organisations (Andres et al., 2012). We use
 20 four main datasets for historical emissions (1751-2016):

- 21 1. Global and national emission estimates from CDIAC for the time period 1751-2014 (Boden
 22 et al., 2017), as it is the only data set that extends back to 1751 by country.
- 23 2. Official UNFCCC national inventory reports for 1990-2015 for the 42 Annex I countries in
 24 the UNFCCC (UNFCCC, 2017), as we assess these to be the most accurate estimates and
 25 are periodically reviewed.
- 26 3. The BP Statistical Review of World Energy (BP, 2017), to project the emissions forward to
 27 2016 to ensure the most recent estimates possible.
- 28 4. The US Geological Survey estimates of cement production (USGS, 2017), to estimate
 29 cement emissions.

1 In the following we provide more details in each dataset and additional modifications that are
2 required to make the dataset consistent and usable.

3 *CDIAC*: The CDIAC estimates have been updated annually to include the most recent year (2014)
4 and to include statistical revisions to recent historical data (UN, 2017). Fuel masses and volumes
5 are converted to fuel energy content using country-level coefficients provided by the UN, and
6 then converted to CO₂ emissions using conversion factors that take into account the relationship
7 between carbon content and energy (heat) content of the different fuel types (coal, oil, gas, gas
8 flaring) and the combustion efficiency (Marland and Rotty, 1984).

9 *UNFCCC*: Estimates from the UNFCCC national inventory reports follow the IPCC guidelines (IPCC,
10 2006), but have a slightly larger system boundary than CDIAC by including emissions coming from
11 carbonates other than in cement manufacture. We reallocate the detailed UNFCCC estimates to
12 the CDIAC definitions of coal, oil, gas, cement, and other to allow consistent comparisons over
13 time and between countries.

14 *BP*: For the most recent period when the UNFCCC (2016) and CDIAC (2015-2016) estimates are not
15 available, we generate preliminary estimates using the BP Statistical Review of World Energy
16 (Andres et al., 2014; Myhre et al., 2009). We apply the BP growth rates by fuel type (coal, oil, gas)
17 to estimate 2016 emissions based on 2015 estimates (UNFCCC), and to estimate 2015 and 2016
18 based on 2014 estimates (CDIAC). BP's dataset explicitly covers about 70 countries (96% of global
19 emissions), and for the remaining countries we use growth rates from the sub-region the country
20 belongs to. For the most recent years, flaring is assumed constant from the most recent available
21 year of data (2015 for countries that report to the UNFCCC, 2014 for the remainder).

22 *USGS*: Estimates of emissions from cement production are based on USGS (USGS, 2017), applying
23 the emission factors from CDIAC (Marland and Rotty, 1984). The CDIAC cement emissions are
24 known to be high, and are likely to be revised downwards next year (Andrew, 2017). Some
25 fraction of the CaO and MgO in cement is returned to the carbonate form during cement
26 weathering but this is omitted here (Xi et al., 2016).

27 *Country mappings*: The published CDIAC data set includes 256 countries and regions. This list
28 includes countries that no longer exist, such as the USSR and Yugoslavia. We reduce the list to 220
29 countries by reallocating emissions to the currently defined territories, using mass-preserving
30 aggregation or disaggregation. Examples of aggregation include merging East and West Germany

1 to the currently defined Germany. Examples of disaggregation include reallocating the emissions
2 from former USSR to the resulting independent countries. For disaggregation, we use the emission
3 shares when the current territories first appeared, and thus historical estimates of disaggregated
4 countries should be treated with extreme care.

5 *Global total:* Our global estimate is based on CDIAC, and this is greater than the sum of emissions
6 from all countries. This is largely attributable to emissions that occur in international territory, in
7 particular, the combustion of fuels used in international shipping and aviation (bunker fuels). The
8 emissions from international bunker fuels are calculated based on where the fuels were loaded,
9 but we do not include them in the national emissions estimates. Other differences occur 1)
10 because the sum of imports in all countries is not equal to the sum of exports, and 2) because of
11 inconsistent national reporting, differing treatment of oxidation of non-fuel uses of hydrocarbons
12 (e.g. as solvents, lubricants, feedstocks, etc.), and 3) changes in fuel stored (Andres et al., 2012).

13 **2.1.2 Uncertainty assessment for E_{FF}**

14 We estimate the uncertainty of the global emissions from fossil fuels and industry at $\pm 5\%$ (scaled
15 down from the published $\pm 10\%$ at $\pm 2\sigma$ to the use of $\pm 1\sigma$ bounds reported here; Andres et al.,
16 2012). This is consistent with a more detailed recent analysis of uncertainty of $\pm 8.4\%$ at $\pm 2\sigma$
17 (Andres et al., 2014) and at the high-end of the range of $\pm 5\text{--}10\%$ at $\pm 2\sigma$ reported by Ballantyne et
18 al. (2015). This includes an assessment of uncertainties in the amounts of fuel consumed, the
19 carbon and heat contents of fuels, and the combustion efficiency. While we consider a fixed
20 uncertainty of $\pm 5\%$ for all years, the uncertainty as a percentage of the emissions is growing with
21 time because of the larger share of global emissions from emerging economies and developing
22 countries (Marland et al., 2009). Generally, emissions from mature economies with good
23 statistical processes have an uncertainty of only a few per cent (Marland, 2008), while developing
24 countries such as China have uncertainties of around $\pm 10\%$ (for $\pm 1\sigma$; Gregg et al., 2008).

25 Uncertainties of emissions are likely to be mainly systematic errors related to underlying biases of
26 energy statistics and to the accounting method used by each country.

27 We assign a medium confidence to the results presented here because they are based on indirect
28 estimates of emissions using energy data (Durant et al., 2011). There is only limited and indirect
29 evidence for emissions, although there is a high agreement among the available estimates within
30 the given uncertainty (Andres et al., 2014; Andres et al., 2012), and emission estimates are

1 consistent with a range of other observations (Ciais et al., 2013), even though their regional and
2 national partitioning is more uncertain (Francey et al., 2013).

3 **2.1.3 Emissions embodied in goods and services**

4 CDIAC, UNFCCC, and BP national emission statistics ‘include greenhouse gas emissions and
5 removals taking place within national territory and offshore areas over which the country has
6 jurisdiction’ (Rypdal et al., 2006), and are called territorial emission inventories. Consumption-
7 based emission inventories allocate emissions to products that are consumed within a country,
8 and are conceptually calculated as the territorial emissions minus the ‘embodied’ territorial
9 emissions to produce exported products plus the emissions in other countries to produce
10 imported products ($\text{Consumption} = \text{Territorial} - \text{Exports} + \text{Imports}$). Consumption-based emission
11 attribution results (e.g. Davis and Caldeira, 2010) provide additional information to territorial-
12 based emissions that can be used to understand emission drivers (Hertwich and Peters, 2009) and
13 quantify emission transfers by the trade of products between countries (Peters et al., 2011b). The
14 consumption-based emissions have the same global total, but reflect the trade-driven movement
15 of emissions across the Earth's surface in response to human activities.

16 We estimate consumption-based emissions from 1990-2015 by enumerating the global supply
17 chain using a global model of the economic relationships between economic sectors within and
18 between every country (Andrew and Peters, 2013; Peters et al., 2011a). Our analysis is based on
19 the economic and trade data from the Global Trade and Analysis Project (GTAP; Narayanan et al.,
20 2015), and we make detailed estimates for the years 1997 (GTAP version 5), 2001 (GTAP6), and
21 2004, 2007, and 2011 (GTAP9.2), covering 57 sectors and 141 countries and regions. The detailed
22 results are then extended into an annual time-series from 1990 to the latest year of the Gross
23 Domestic Product (GDP) data (2015 in this budget), using GDP data by expenditure in current
24 exchange rate of US dollars (USD; from the UN National Accounts main Aggregates database; UN,
25 2016) and time series of trade data from GTAP (based on the methodology in Peters et al., 2011b
26). We estimate the sector-level CO₂ emissions using the GTAP data and methodology, include
27 flaring and cement emissions from CDIAC, and then scale the national totals (excluding bunker
28 fuels) to match the emission estimates from the carbon budget. We do not provide a separate
29 uncertainty estimate for the consumption-based emissions, but based on model comparisons and
30 sensitivity analysis, they are unlikely to be significantly different than for the territorial emission
31 estimates (Peters et al., 2012a).

1 **2.1.4 Growth rate in emissions**

2 We report the annual growth rate in emissions for adjacent years (in percent per year) by
 3 calculating the difference between the two years and then comparing to the emissions in the first
 4 year: $(E_{FF}(t_{0+1}) - E_{FF}(t_0)) / E_{FF}(t_0) \times 100\% \text{yr}^{-1}$. We apply a leap-year adjustment to ensure valid
 5 interpretations of annual growth rates. This affects the growth rate by about $0.3\% \text{yr}^{-1}$ ($1/365$) and
 6 causes growth rates to go up approximately 0.3% if the first year is a leap year and down 0.3% if
 7 the second year is a leap year.

8 The relative growth rate of E_{FF} over time periods of greater than one year can be re-written using
 9 its logarithm equivalent as follows:

$$\frac{1}{E_{FF}} \frac{dE_{FF}}{dt} = \frac{d(\ln E_{FF})}{dt} \quad (2)$$

10 Here we calculate relative growth rates in emissions for multi-year periods (e.g. a decade) by
 11 fitting a linear trend to $\ln(E_{FF})$ in Eq. (2), reported in percent per year.

12 **2.1.5 Emissions projections**

13 To gain insight on emission trends for the current year (2017), we provide an assessment of global
 14 fossil fuel and industry emissions, E_{FF} , by combining individual assessments of emissions for China,
 15 USA, India (the three countries with the largest emissions), and the rest of the world. Although the
 16 EU in aggregate emits more than India, neither official forecasts nor monthly energy statistics are
 17 available for the EU as a whole. In consequence, we use GDP projections to infer the emissions for
 18 this region.

19 Our 2017 estimate for China uses: (1) estimates of coal consumption, production, imports and
 20 inventory changes from the China Coal Industry Association (CCIA) and the National Energy
 21 Agency of China (NEA) for January through June (CCIA, 2017; NEA, 2017) (2) estimated
 22 consumption of natural gas and petroleum for January through June from NEA (CCIA, 2017; NEA,
 23 2017) and (3) production of cement reported for January through August (NBS, 2017). Using these
 24 data, we estimate the change in emissions for the corresponding months in 2017 compared to
 25 2016 assuming no change in the energy and carbon content of coal for 2017. We then use a
 26 central estimate for the growth rate of the whole year that is adjusted down somewhat relative to
 27 the first half of the year, to account for a slowing trend in industrial growth observed since July
 28 and qualitative statements from the NEA saying that they expect oil and coal consumption to be

1 relatively stable for the second half of the year. The main sources of uncertainty are from
 2 inconsistencies between available data sources, incomplete data on inventory changes, the
 3 carbon content of coal and the assumptions for the behaviour for the rest of the year. These are
 4 discussed further in Sect. 3.2.1.

5 For the USA, we use the forecast of the U.S. Energy Information Administration (EIA) for emissions
 6 from fossil fuels (EIA, 2017). This is based on an energy forecasting model which is revised
 7 monthly, and takes into account heating-degree days, household expenditures by fuel type,
 8 energy markets, policies, and other effects. We combine this with our estimate of emissions from
 9 cement production using the monthly U.S. cement data from USGS for January-June, assuming
 10 changes in cement production over the first part of the year apply throughout the year. While the
 11 EIA's forecasts for current full-year emissions have on average been revised downwards, only nine
 12 such forecasts are available, so we conservatively use the full range of adjustments following
 13 revision, and additionally assume symmetrical uncertainty to give $\pm 2.7\%$ around the central
 14 forecast.

15 For India, we use (1) coal production and sales data from the Ministry of Mines, Coal India Limited
 16 (CIL, 2017; Ministry of Mines, 2017) and Singareni Collieries Company Limited (SCCL, 2017),
 17 combined with imports data from the Ministry of Commerce and Industry (MCI, 2017) and power
 18 station stocks data from the Central Electricity Authority (CEA, 2017), (2) oil production and
 19 consumption data from the Ministry of Petroleum and Natural Gas (PPAC, 2017b), (3) natural gas
 20 production and import data from the Ministry of Petroleum and Natural Gas (PPAC, 2017a), and
 21 (4) cement production data from the Office of the Economic Advisor (OEA, 2017). The main source
 22 of uncertainty in the projection of India's emissions is the assumption of persistent growth for the
 23 rest of the year.

24 For the rest of the world, we use the close relationship between the growth in GDP and the
 25 growth in emissions (Raupach et al., 2007) to project emissions for the current year. This is based
 26 on a simplified Kaya Identity, whereby E_{FF} (GtC yr^{-1}) is decomposed by the product of GDP (USD yr^{-1})
 27 and the fossil fuel carbon intensity of the economy (I_{FF} ; GtC USD^{-1}) as follows:

$$E_{FF} = \text{GDP} \times I_{FF} \quad (3)$$

28 Taking a time derivative of Equation (3) and rearranging gives:

$$\frac{1}{E_{FF}} \frac{dE_{FF}}{dt} = \frac{1}{GDP} \frac{dGDP}{dt} + \frac{1}{I_{FF}} \frac{dI_{FF}}{dt} \quad (4)$$

1 where the left-hand term is the relative growth rate of E_{FF} , and the right-hand terms are the
 2 relative growth rates of GDP and I_{FF} , respectively, which can simply be added linearly to give the
 3 overall growth rate.

4 The growth rates are reported in percent by multiplying each term by 100. As preliminary
 5 estimates of annual change in GDP are made well before the end of a calendar year, making
 6 assumptions on the growth rate of I_{FF} allows us to make projections of the annual change in CO_2
 7 emissions well before the end of a calendar year. The I_{FF} is based on GDP in constant PPP
 8 (purchasing power parity) from the IEA up to 2014 (IEA/OECD, 2016) and extended using the IMF
 9 growth rates for 2015 and 2016 (IMF, 2017). Interannual variability in I_{FF} is the largest source of
 10 uncertainty in the GDP-based emissions projections. We thus use the standard deviation of the
 11 annual I_{FF} for the period 2006-2016 as a measure of uncertainty, reflecting a $\pm 1\sigma$ as in the rest of
 12 the carbon budget. This is $\pm 1.1\% \text{ yr}^{-1}$ for the rest of the world (global emissions minus China, USA,
 13 and India).

14 The 2017 projection for the world is made of the sum of the projections for China, USA, India, and
 15 the rest. The uncertainty is added in quadrature among the three regions. The uncertainty here
 16 reflects the best of our expert opinion.

17 **2.2 CO_2 emissions from land use, land-use change and forestry (E_{LUC})**

18 Land-use change emissions reported here (E_{LUC}) include CO_2 fluxes from deforestation,
 19 afforestation, logging (forest degradation and harvest activity), shifting cultivation (cycle of cutting
 20 forest for agriculture, then abandoning), and regrowth of forests following wood harvest or
 21 abandonment of agriculture. Only some land management activities are included in our land-use
 22 change emissions estimates (Table 4a). Some of these activities lead to emissions of CO_2 to the
 23 atmosphere, while others lead to CO_2 sinks. E_{LUC} is the net sum of all anthropogenic activities
 24 considered. Our annual estimate for 1959-2016 is provided as the average of results from two
 25 bookkeeping models (Sect. 2.2.1): the estimate published by Houghton and Nassikas (2017;
 26 hereafter H&N2017) extended here to 2016, and the average of two simulations done with the
 27 BLUE model (“bookkeeping of land use emissions”; Hansis et al., 2015). In addition, we use results
 28 from DGVMs (see Sect. 2.2.3 and Table 4a), to help quantify the uncertainty in E_{LUC} , and to explore

1 the consistency of our understanding. The three methods are described below, and differences
2 are discussed in Sect. 3.2.

3 **2.2.1 Bookkeeping models**

4 Land-use change CO₂ emissions and uptake fluxes are calculated by two bookkeeping models.
5 Both are based on the original bookkeeping approach of Houghton (2003) that keeps track of the
6 carbon stored in vegetation and soils before and after a land-use change (transitions between
7 various natural vegetation types, croplands and pastures). Literature-based response curves
8 describe decay of vegetation and soil carbon, including transfer to product pools of different
9 lifetimes, as well as carbon uptake due to regrowth. Additionally, it represents permanent
10 degradation of forests by lower vegetation and soil carbon stocks for secondary as compared to
11 the primary forests and forest management such as wood harvest.

12 The bookkeeping models do not include land ecosystems' transient response to changes in
13 climate, atmospheric CO₂ and other environmental factors, and the carbon densities are based on
14 contemporary data reflecting stable environmental conditions at that time. Since carbon densities
15 remain fixed over time in bookkeeping models, the additional sink capacity that ecosystems
16 provide in response to CO₂-fertilization and other environmental changes is not captured by these
17 models (Pongratz et al., 2014; see Section 2.7.3).

18 The H&N and BLUE models differ in (1) computational units (country-level vs spatially explicit
19 treatment of land-use change), (2) processes represented (see Table 4a), and (3) carbon densities
20 assigned to vegetation and soil of each vegetation type. A notable change of H&N over the
21 original approach by Houghton et al. (2003) used in earlier budget estimates is that no shifting
22 cultivation or other back- and forth-transitions at a level below country level are included. Only a
23 decline in forest area in a country as indicated by the Forest Resource Assessment of the FAO that
24 exceeds the expansion of agricultural area as indicated by FAO is assumed to represent a
25 concurrent expansion and abandonment of cropland. In contrast, the BLUE model includes sub-
26 grid-scale transitions at the grid level between all vegetation types as indicated by the harmonized
27 land-use change data (LUH2) dataset (Hurtt et al., in prep.). Furthermore, H&N assume conversion
28 of natural grasslands to pasture, while BLUE allocates pasture proportionally on all natural
29 vegetation that exist in a gridcell. This is one reason for generally higher emissions in BLUE. H&N
30 add carbon emissions from peat burning based on the Global Fire Emission Database (GFED4s; van

1 der Werf et al. (2017)), and peat drainage, based on estimates by Hooijer et al. (2010) to the
2 output of their bookkeeping model for the countries of Indonesia and Malaysia. Peat burning and
3 emissions from the organic layers of drained peat soils, which are not captured by bookkeeping
4 methods directly, need to be included to represent the substantially larger emissions and
5 interannual variability due to synergies of land-use change and climate variability in South East
6 Asia, in particular during El-Niño events. Similarly to H&N, peat burning and drainage-related
7 emissions are also added to the BLUE estimate based on GFED4s (van der Werf et al., 2017),
8 adding the peat burning for the GFED region of equatorial Asia, and the peat drainage for
9 Southeast Asia from Hooijer et al (2010).

10 The two bookkeeping estimates used in this study also differ with respect to the land-cover
11 change data used to drive the models. H&N base their estimates directly on the Forest Resource
12 Assessment of the FAO which provides statistics on forest-cover change and management at
13 intervals of five years (FAO, 2015). The data is based on countries' self-reporting, some of which
14 include satellite data in more recent assessments. Changes in land cover other than forests are
15 based on annual, national changes in cropland and pasture areas reported by the FAO Statistics
16 Division (FAOSTAT, 2015). BLUE uses the harmonized land-use change data LUH2 (Hurtt et al., in
17 prep.) which describes land cover change, also based on the FAO data, but downscaled at a
18 quarter-degree spatial resolution, considering sub-grid-scale transitions between primary forest,
19 secondary forest, cropland, pasture and rangeland. The new LUH2 data provides a new distinction
20 between rangelands and pasture. This is implemented by assuming rangelands are treated either
21 all as pastures, or all as natural vegetation. These two assumptions are then averaged to provide
22 the BLUE result that is closest to the expected real value.

23 The estimate of H&N was extended here by one year (to 2016) by adding the anomaly of total
24 peat emissions (burning and drainage) from GFED4s over the previous decade (2006-2015) to the
25 decadal average of the bookkeeping result. A small correction to their 2015 value was also made
26 based on the updated peat burning of GFED4s.

27 **2.2.2 Dynamic Global Vegetation Models (DGVMs)**

28 Land-use change CO₂ emissions have also been estimated using an ensemble of 12 DGVM
29 simulations. The DGVMs account for deforestation and regrowth, the most important
30 components of E_{LUC}, but they do not represent all processes resulting directly from human

1 activities on land (Table 4a). All DGVMs represent processes of vegetation growth and mortality,
 2 as well as decomposition of dead organic matter associated with natural cycles, and include the
 3 vegetation and soil carbon response to increasing atmospheric CO₂ levels and to climate variability
 4 and change. Some models explicitly simulate the coupling of carbon and nitrogen cycles and
 5 account for atmospheric N deposition (Table 4a). The DGVMs are independent from the other
 6 budget terms except for their use of atmospheric CO₂ concentration to calculate the fertilization
 7 effect of CO₂ on plant photosynthesis.

8 The DGVMs used the HYDE land-use change data set (Klein Goldewijk et al., in press.; Klein
 9 Goldewijk et al., 2017), which provides annual, half-degree, fractional data on cropland and
 10 pasture. These data are based on annual FAO statistics of change in agricultural area available to
 11 2012 (FAOSTAT, 2015). For the years 2015 and 2016, the HYDE data were extrapolated by country
 12 for pastures and cropland separately based on the trend in agricultural area over the previous 5
 13 years. Some models also use an update of the more comprehensive harmonised land-use data set
 14 (Hurtt et al., 2011), that further includes fractional data on primary vegetation and secondary
 15 vegetation, as well as all underlying transitions between land-use states (Hurtt et al., in prep.).
 16 This new dataset is of quarter degree fractional areas of land use states and all transitions
 17 between those states, including a new wood harvest reconstruction, new representation of
 18 shifting cultivation, crop rotations, management information including irrigation and fertilizer
 19 application. The land-use states now include two different pasture/grazing types, and 5 different
 20 crop types. Wood harvest patterns are constrained with Landsat forest loss data.

21 DGVMs implement land-use change differently (e.g. an increased cropland fraction in a grid cell
 22 can either be at the expense of grassland or shrubs, or forest, the latter resulting in deforestation;
 23 land cover fractions of the non-agricultural land differ between models). Similarly, model-specific
 24 assumptions are applied to convert deforested biomass or deforested area, and other forest
 25 product pools into carbon, and different choices are made regarding the allocation of rangelands
 26 as natural vegetation or pastures.

27 The DGVM model runs were forced by either 6 hourly CRU-NCEP or by monthly CRU temperature,
 28 precipitation, and cloud cover fields (transformed into incoming surface radiation) based on
 29 observations and provided on a 0.5°x0.5° grid and updated to 2016 (Harris et al., 2014; Viovy,
 30 2016). The forcing data include both gridded observations of climate and global atmospheric CO₂,

1 which change over time (Dlugokencky and Tans, 2017), and N deposition (as used in some models;
2 Table 4a).

3 Two sets of simulations were performed with the DGVMs. The first forced initially with historical
4 changes in land cover distribution, climate, atmospheric CO₂ concentration, and N deposition, and
5 the second, as further described below, with a time-invariant preindustrial land cover distribution,
6 allowing the models to estimate, by difference with the first simulation, the dynamic evolution of
7 biomass and soil carbon pools in response to prescribed land-cover change. E_{LUC} is diagnosed in
8 each model by the difference between these two simulations. We only retain model outputs with
9 positive E_{LUC} during the 1990s. Using the difference between these two DGVM simulations to
10 diagnose E_{LUC} means the DGVMs account for the loss of additional sink capacity (around 0.3 GtC
11 yr⁻¹; see Section 2.7.3), while the bookkeeping models do not.

12 **2.2.3 Uncertainty assessment for E_{LUC}**

13 Differences between the bookkeeping models and DGVM models originate from three main
14 sources: the land cover change data set, the different approaches used in models, and the
15 different processes represented (Table 4a). We examine the results from the DGVM models and
16 of the bookkeeping method to assess the uncertainty in E_{LUC}.

17 The E_{LUC} estimate from the DGVMs multi-model mean is consistent with the average of the
18 emissions from the bookkeeping models (Table 6). However there are large differences among
19 individual DGVMs (standard deviation at around 0.5-0.6 GtC yr⁻¹; Table 6), between the two
20 bookkeeping models (average of 0.5 GtC yr⁻¹), and between the current estimate of H&N and its
21 previous model version (Houghton et al., 2012) as used in past Global Carbon Budgets (Le Quéré
22 et al. 2016; average of 0.3 GtC yr⁻¹). Given the large spread in new estimates we raise our
23 assessment of uncertainty in E_{LUC} to ±0.7 GtC yr⁻¹ (from 0.5 GtC yr⁻¹) as a semi-quantitative
24 measure of uncertainty for annual emissions. This reflects our best value judgment that there is at
25 least 68% chance (±1σ) that the true land-use change emission lies within the given range, for the
26 range of processes considered here. Prior to 1959, the uncertainty in E_{LUC} was taken from the
27 standard deviation of the DGVMs. We assign low confidence to the annual estimates of E_{LUC}
28 because of the inconsistencies among estimates and of the difficulties to quantify some of the
29 processes in DGVMs.

1 **2.2.4 Emissions projections**

2 We provide an assessment of E_{LUC} for 2017 by adding the anomaly of fire emissions in
 3 deforestation areas, including those from peat fires, from GFED4s (van der Werf et al., 2017) over
 4 the last year available. Emissions are estimated using active fire data (MCD14ML; Giglio et al.
 5 (2003)), which are available in near-real time, and correlations between those and GFED4s
 6 emissions for the 2001-2016 period for 12 the corresponding months. Emissions during January-
 7 October cover most of the fires season in the Amazon and Southeast Asia, where a large part of
 8 the global deforestation takes place.

9 **2.3 Growth rate in atmospheric CO₂ concentration (G_{ATM})**

10 **2.3.1 Global growth rate in atmospheric CO₂ concentration**

11 The rate of growth of the atmospheric CO₂ concentration is provided by the US National Oceanic
 12 and Atmospheric Administration Earth System Research Laboratory (NOAA/ESRL; Dlugokencky
 13 and Tans, 2017), which is updated from Ballantyne et al. (2012). For the 1959-1980 period, the
 14 global growth rate is based on measurements of atmospheric CO₂ concentration averaged from
 15 the Mauna Loa and South Pole stations, as observed by the CO₂ Program at Scripps Institution of
 16 Oceanography (Keeling et al., 1976). For the 1980-2016 time period, the global growth rate is
 17 based on the average of multiple stations selected from the marine boundary layer sites with well-
 18 mixed background air (Ballantyne et al., 2012), after fitting each station with a smoothed curve as
 19 a function of time, and averaging by latitude band (Masarie and Tans, 1995). The annual growth
 20 rate is estimated by Dlugokencky and Tans (2017) from atmospheric CO₂ concentration by taking
 21 the average of the most recent December-January months corrected for the average seasonal
 22 cycle and subtracting this same average one year earlier. The growth rate in units of ppm yr⁻¹ is
 23 converted to units of GtC yr⁻¹ by multiplying by a factor of 2.12 GtC per ppm (Ballantyne et al.,
 24 2012).

25 The uncertainty around the annual growth rate based on the multiple stations data set ranges
 26 between 0.11 and 0.72 GtC yr⁻¹, with a mean of 0.61 GtC yr⁻¹ for 1959-1979 and 0.19 GtC yr⁻¹ for
 27 1980-2016, when a larger set of stations were available (Dlugokencky and Tans, 2017). It is based
 28 on the number of available stations, and thus takes into account both the measurement errors
 29 and data gaps at each station. This uncertainty in decadal change is computed from the difference
 30 in concentration ten years apart based on a measurement error of 0.35 ppm. This error is based

1 on offsets between NOAA/ESRL measurements and those of the World Meteorological
2 Organization World Data Centre for Greenhouse Gases (NOAA/ESRL, 2015) for the start and end
3 points (the decadal change uncertainty is the $\sqrt{(2(0.35\text{ppm})^2)(10\text{ yr})^{-1}}$ assuming that each
4 yearly measurement error is independent).

5 We assign a high confidence to the annual estimates of G_{ATM} because they are based on direct
6 measurements from multiple and consistent instruments and stations distributed around the
7 world (Ballantyne et al., 2012).

8 In order to estimate the total carbon accumulated in the atmosphere since 1750 or 1870, we use
9 an atmospheric CO_2 concentration of 277 ± 3 ppm or 288 ± 3 ppm, respectively, based on a cubic
10 spline fit to ice core data (Joos and Spahni, 2008). The uncertainty of ± 3 ppm (converted to $\pm 1\sigma$) is
11 taken directly from the IPCC's assessment (Ciais et al., 2013). Typical uncertainties in the growth
12 rate in atmospheric CO_2 concentration from ice core data are equivalent to $\pm 0.1\text{--}0.15\text{ GtC yr}^{-1}$ as
13 evaluated from the Law Dome data (Etheridge et al., 1996) for individual 20-year intervals over
14 the period from 1870 to 1960 (Bruno and Joos, 1997).

15 **2.3.2 Growth rate projection**

16 We provide an assessment of G_{ATM} for 2017 based on the observed increase in atmospheric CO_2
17 concentration at the Mauna Loa station for January to September, and monthly forecasts for
18 October to December updated from Betts et al. (2016). The forecast uses a statistical relationship
19 between annual CO_2 growth rate and sea surface temperatures (SSTs) in the Niño3.4 region. The
20 forecast SSTs from the GLOSEA seasonal forecast model was then used to estimate monthly CO_2
21 concentrations at Mauna Loa throughout the following calendar year, assuming a stationary
22 seasonal cycle. The forecast CO_2 concentrations for January to August 2017 were close to the
23 observations, so updating the 2017 forecast by simply averaging the observed and forecast values
24 is considered justified. Growth at Mauna Loa is closely correlated with the global growth ($r=0.95$)
25 and is used here as a proxy for global growth.

26 **2.4 Ocean CO_2 sink**

27 Estimates of the global ocean CO_2 sink S_{OCEAN} are from an ensemble of global ocean
28 biogeochemistry models (GOBM) that meet observational constraints over the 1990s (see below).
29 We use observation-based estimates of S_{OCEAN} to provide a qualitative assessment of confidence in

1 the reported results, and to estimate the cumulative accumulation of S_{OCEAN} over the preindustrial
2 period.

3 **2.4.1 Observation-based estimates**

4 We use the observational constraints assessed by IPCC of a mean ocean CO_2 sink of $2.2 \pm 0.4 \text{ GtC}$
5 yr^{-1} for the 1990s (Denman et al., 2007) to verify that the GOBMs provide a realistic assessment of
6 S_{OCEAN} . This is based on indirect observations and their spread: ocean/land CO_2 sink partitioning
7 from observed atmospheric O_2/N_2 concentration trends (Manning and Keeling, 2006; updated in
8 Keeling and Manning 2014), an oceanic inversion method constrained by ocean biogeochemistry
9 data (Mikaloff Fletcher et al., 2006), and a method based on penetration time scale for CFCs
10 (McNeil et al., 2003). This estimate is consistent with a range of methods (Wanninkhof et al.,
11 2013). All GOBMs fall within 90% confidence of the observed range, or 1.6 to 2.8 GtC yr^{-1} for the
12 1990s.

13 We use two estimates of the ocean CO_2 sink and its variability based on interpolations of
14 measurements of surface ocean fugacity of CO_2 ($p\text{CO}_2$ corrected for the non-ideal behaviour of
15 the gas; Pfeil et al., 2013). We refer to these as $p\text{CO}_2$ -based flux estimates. The measurements are
16 from the Surface Ocean CO_2 Atlas version 5, which is an update of version 3 (Bakker et al., 2016)
17 and contains quality-controlled data to 2016 (see data attribution Table A2). The SOCAT v5 were
18 mapped using a data-driven diagnostic method (Rödenbeck et al., 2013) and a combined self-
19 organising map and feed-forward neural network (Landschützer et al., 2014). The global $p\text{CO}_2$ -
20 based flux estimates were adjusted to remove the preindustrial ocean source of CO_2 to the
21 atmosphere of 0.45 GtC yr^{-1} from river input to the ocean (Jacobson et al., 2007), per our
22 definition of S_{OCEAN} . Several other flux products are available, but they show large discrepancies
23 with observed variability that need to be resolved. Here we used the two $p\text{CO}_2$ -based flux
24 products that had the best fit to observations for their representation of tropical and global
25 variability (Rödenbeck et al., 2015).

26 We further use results from two diagnostic ocean models of Khatiwala et al. (2013) and DeVries et
27 al. (2014) to estimate the anthropogenic carbon accumulated in the ocean prior to 1959. The two
28 approaches assume constant ocean circulation and biological fluxes over the preindustrial period,
29 with S_{OCEAN} estimated as a response in the change in atmospheric CO_2 concentration calibrated to
30 observations. The uncertainty in cumulative uptake of $\pm 20 \text{ GtC}$ (converted to $\pm 1\sigma$) is taken directly

1 from the IPCC's review of the literature (Rhein et al., 2013), or about $\pm 30\%$ for the annual values
2 (Khatiwala et al., 2009).

3 **2.4.2 Global Ocean Biogeochemistry Models (GOBM)**

4 The ocean CO_2 sink for 1959-2016 is estimated using eight GOBM (Table 4b) that meet
5 observational constraints for the mean ocean sink in the 1990s. The GOBM represent the physical,
6 chemical and biological processes that influence the surface ocean concentration of CO_2 and thus
7 the air-sea CO_2 flux. The GOBM are forced by meteorological reanalysis and atmospheric CO_2
8 concentration data available for the entire time period, and mostly differ in the source of the
9 atmospheric forcing data, spin up strategies, and in the resolution of the oceanic physical
10 processes (Table 4b). GOBMs do not include the effects of anthropogenic changes in nutrient
11 supply, which could lead to an increase of the ocean sink of up to about 0.3 GtC yr^{-1} over the
12 industrial period (Duce et al., 2008). They also do not include the perturbation associated with
13 changes in river organic carbon, which is discussed Sect. 2.7.

14 The ocean CO_2 sink for each GOBM is no longer normalised to the observations as in previous
15 global carbon budgets (e.g. Le Quéré et al. 2016). The normalisation was mostly intended to
16 ensure S_{LAND} had a realistic mean value as it was previously estimated from the budget residual.
17 With the introduction of the budget residual (Eq. 1) all terms can be estimated independently.
18 Rather the oceanic observations are used in the selection of the GOBM, by using only the GOBM
19 that produce an oceanic CO_2 sink over the 1990s consistent with observations, as explained
20 above.

21 **2.4.3 Uncertainty assessment for S_{OCEAN}**

22 The uncertainty around the mean ocean sink of anthropogenic CO_2 was quantified by Denman et
23 al. (2007) for the 1990s (see Sect. 2.4.1). To quantify the uncertainty around annual values, we
24 examine the standard deviation of the GOBM ensemble, which averages between 0.2 and 0.3 GtC
25 yr^{-1} during 1959-2017. We estimate that the uncertainty in the annual ocean CO_2 sink is about \pm
26 0.5 GtC yr^{-1} from the combined uncertainty of the mean flux based on observations of $\pm 0.4 \text{ GtC yr}^{-1}$
27 and the standard deviation across GOBMs of up to $\pm 0.3 \text{ GtC yr}^{-1}$, reflecting both the uncertainty
28 in the mean sink from observations during the 1990's (Denman et al., 2007; Section 2.4.1) and in
29 the interannual variability as assessed by GOBMs.

1 We examine the consistency between the variability of the model-based and the pCO₂-based flux
2 products to assess confidence in S_{OCEAN}. The interannual variability of the ocean fluxes (quantified
3 as the standard deviation) of the two pCO₂-based products for 1986-2016 (where they overlap) is
4 $\pm 0.35 \text{ GtC yr}^{-1}$ (Rödenbeck et al., 2014) and $\pm 0.36 \text{ GtC yr}^{-1}$ (Landschützer et al., 2015), compared
5 to $\pm 0.27 \text{ GtC yr}^{-1}$ for the normalised GOBM ensemble. The standard deviation includes a
6 component of trend and decadal variability in addition to interannual variability, and their relative
7 influence differs across estimates. The estimates generally produce a higher ocean CO₂ sink during
8 strong El Niño events. The annual pCO₂-based flux products correlate with the ocean CO₂ sink
9 estimated here with a correlation of $r = 0.75$ (0.49 to 0.84 for individual GOBMs), and $r = 0.78$
10 (0.46 to 0.80) for the pCO₂-based flux products of Rödenbeck et al. (2014) and Landschützer et al.
11 (2015), respectively (simple linear regression), with their mutual correlation at 0.70. The
12 agreement is better for decadal variability than for interannual variability. The use of annual data
13 for the correlation may reduce the strength of the relationship because the dominant source of
14 variability associated with El Niño events is less than one year. We assess a medium confidence
15 level to the annual ocean CO₂ sink and its uncertainty because it is based on multiple lines of
16 evidence, and the results are consistent in that the interannual variability in the GOBMs and data-
17 based estimates are all generally small compared to the variability in the growth rate of
18 atmospheric CO₂ concentration.

19 **2.5 Terrestrial CO₂ sink**

20 The terrestrial land sink (S_{LAND}) is thought to be due to the combined effects of fertilisation by
21 rising atmospheric CO₂ and N deposition on plant growth, as well as the effects of climate change
22 such as the lengthening of the growing season in northern temperate and boreal areas. S_{LAND} does
23 not include gross land sinks directly resulting from land-use change (e.g. regrowth of vegetation)
24 as these are part of the net land use flux (E_{LUC}), although system boundaries make it difficult to
25 attribute exactly CO₂ fluxes on land between S_{LAND} and E_{LUC} (Erb et al., 2013).

26 New to the 2017 Global Carbon Budget, S_{LAND} is estimated from the multi-model mean of the
27 DGVMs (Table 4a). As described in Sect. 2.2.3, DGVM simulations include all climate variability and
28 CO₂ effects over land. The DGVMs do not include the perturbation associated with changes in
29 river organic carbon, which is discussed Sect. 2.7. We apply three criteria for minimum DGVM
30 realism by including only those DGVMs with (1) steady state after spin up, (2) where available, net
31 land fluxes (S_{LAND} – E_{LUC}) that is a carbon sink over the 1990s between -0.3 and 2.3 GtC yr^{-1} , within

1 90% confidence of constraints by global atmospheric and oceanic observations (Keeling and
2 Manning, 2014; Wanninkhof et al., 2013), and (3) global E_{LUC} that is a carbon source over the
3 1990s.

4 The standard deviation of the annual CO_2 sink across the DGVMs averages to $\pm 0.8 \text{ GtC yr}^{-1}$ for the
5 period 1959 to 2016. We attach a medium confidence level to the annual land CO_2 sink and its
6 uncertainty because the estimates from the residual budget and averaged DGVMs match well
7 within their respective uncertainties (Table 6).

8 **2.6 The atmospheric perspective**

9 The world-wide network of atmospheric measurements can be used with atmospheric inversion
10 methods to constrain the location of the combined total surface CO_2 fluxes from all sources,
11 including fossil and land-use change emissions and land and ocean CO_2 fluxes. The inversions
12 assume E_{FF} to be well known, and they solve for the spatial and temporal distribution of land and
13 ocean fluxes from the residual gradients of CO_2 between stations that are not explained by
14 emissions.

15 Three atmospheric inversions (Table 4c) used atmospheric CO_2 data to the end of 2016 (including
16 preliminary values in some cases) to infer the spatio-temporal CO_2 flux field. We focus here on the
17 largest and most consistent sources of information (namely the total CO_2 flux over land regions,
18 and the distribution of the total land and ocean CO_2 fluxes for the mid-high latitude northern
19 hemisphere (30°N-90°N), Tropics (30°S-30°N) and mid-high latitude region of the southern
20 hemisphere (30°S-90°S)), and use these estimates to comment on the consistency across various
21 data streams and process-based estimates.

22 **Atmospheric inversions**

23 The three inversion systems used in this release are the CarbonTracker Europe (CTE; van der Laan-
24 Luijkx et al., 2017), the Jena CarboScope (Rödenbeck, 2005), and CAMS (Chevallier et al., 2005).
25 See Table 4c for version numbers. The three inversions are based on the same Bayesian inversion
26 principles that interpret the same, for the most part, observed time series (or subsets thereof),
27 but use different methodologies (Table 4c). These differences mainly concern the selection of
28 atmospheric CO_2 data, the used prior fluxes, spatial breakdown (i.e. grid size), assumed
29 correlation structures, and mathematical approach. The details of these approaches are

1 documented extensively in the references provided above. Each system uses a different transport
2 model, which was demonstrated to be a driving factor behind differences in atmospheric-based
3 flux estimates, and specifically their distribution across latitudinal bands (Stephens et al., 2007).

4 The three inversions use atmospheric CO₂ observations from various flask and in situ networks, as
5 detailed in Table 4c. They prescribe global E_{FF}, which is scaled to the present study for CAMS and
6 CTE, while CarboScope uses CDIAC extended after 2013 using the emission growth rate of the
7 present study. Inversion results for the sum of natural ocean and land fluxes (Fig. 8) are more
8 constrained in the Northern hemisphere (NH) than in the Tropics, because of the higher
9 measurement stations density in the NH. Results from atmospheric inversions, similar to the
10 pCO₂-based ocean flux products, need to be corrected for the river fluxes. The atmospheric
11 inversions provide new information on the regional distribution of fluxes.

12 **2.7 Processes not included in the global carbon budget**

13 The contribution of anthropogenic CO and CH₄ to the global carbon budget has been partly
14 neglected in Eq. 1 and is described in Sect. 2.7.1. The contribution of anthropogenic changes in
15 river fluxes is conceptually included in Eq. 1 in S_{OCEAN} and in S_{LAND}, but it is not represented in the
16 process models used to quantify these fluxes. This effect is discussed in Sect. 2.7.2. Similarly, the
17 loss of additional sink capacity from reduced forest cover is missing in the combination of
18 approaches used here to estimate both land fluxes (E_{LUC} and S_{LAND}) and its potential effect is
19 discussed and quantified in Sect. 2.7.3.

20 **2.7.1 Contribution of anthropogenic CO and CH₄ to the global carbon budget**

21 Anthropogenic emissions of CO and CH₄ to the atmosphere are eventually oxidized to CO₂ and
22 thus are part of the global carbon budget. These contributions are omitted in Eq. (1), but an
23 attempt is made in this section to estimate their magnitude, and identify the sources of
24 uncertainty. Anthropogenic CO emissions are from incomplete fossil fuel and biofuel burning and
25 deforestation fires. The main anthropogenic emissions of fossil CH₄ that matter for the global
26 carbon budget are the fugitive emissions of coal, oil and gas upstream sectors (see below). These
27 emissions of CO and CH₄ contribute a net addition of fossil carbon to the atmosphere.

28 In our estimate of E_{FF} we assumed (Sect. 2.1.1) that all the fuel burned is emitted as CO₂, thus CO
29 anthropogenic emissions and their atmospheric oxidation into CO₂ within a few months are

1 already counted implicitly in E_{FF} and should not be counted twice (same for E_{LUC} and
2 anthropogenic CO emissions by deforestation fires). Anthropogenic emissions of fossil CH_4 are not
3 included in E_{FF} , because these fugitive emissions are not included in the fuel inventories. Yet they
4 contribute to the annual CO_2 growth rate after CH_4 gets oxidized into CO_2 . Anthropogenic
5 emissions of fossil CH_4 represent 15% of total CH_4 emissions (Kirschke et al., 2013) that is 0.061
6 $GtC\ yr^{-1}$ for the past decade. Assuming steady state, these emissions are all converted to CO_2 by
7 OH oxidation, and thus explain $0.06\ GtC\ yr^{-1}$ of the global CO_2 growth rate in the past decade, or
8 $0.07\text{--}0.1\ GtC\ yr^{-1}$ using the higher CH_4 emissions reported recently (Schwietzke et al., 2016).
9 Other anthropogenic changes in the sources of CO and CH_4 from wildfires, biomass, wetlands,
10 ruminants or permafrost changes are similarly assumed to have a small effect on the CO_2 growth
11 rate.

12 **2.7.2 Anthropogenic carbon fluxes in the land to ocean aquatic continuum**

13 The approach used to determine the global carbon budget refers to the mean, variations, and
14 trends in the perturbation of CO_2 in the atmosphere, referenced to the preindustrial era. Carbon is
15 continuously displaced from the land to the ocean through the land-ocean aquatic continuum
16 (LOAC) comprising freshwaters, estuaries and coastal areas (Bauer et al., 2013; Regnier et al.,
17 2013). A significant fraction of this lateral carbon flux is entirely ‘natural’ and is thus a steady state
18 component of the preindustrial carbon cycle. We account for this preindustrial flux where
19 appropriate in our study. However, changes in environmental conditions and land use change
20 have caused an increase in the lateral transport of carbon into the LOAC – a perturbation that is
21 relevant for the global carbon budget presented here.

22 The results of the analysis of Regnier et al. (2013) can be summarized in two points of relevance
23 for the anthropogenic CO_2 budget. First, the anthropogenic perturbation has increased the
24 organic carbon export from terrestrial ecosystems to the hydrosphere at a rate of $1.0 \pm 0.5\ GtC\ yr^{-1}$,
25 mainly owing to enhanced carbon export from soils. Second, this exported anthropogenic
26 carbon is partly respired through the LOAC, partly sequestered in sediments along the LOAC and
27 to a lesser extent, transferred in the open ocean where it may accumulate. The increase in storage
28 of land-derived organic carbon in the LOAC and open ocean combined is estimated by Regnier et
29 al. (2013) at $0.65 \pm 0.35\ GtC\ yr^{-1}$. We do not attempt to incorporate the changes in LOAC in our
30 study.

1 The inclusion of freshwater fluxes of anthropogenic CO₂ affects the estimates of, and partitioning
2 between, S_{LAND} and S_{OCEAN} in Eq. (1) in complementary ways, but does not affect the other terms.
3 This effect is not included in the GOBMs and DGVMs used in our global carbon budget analysis
4 presented here.

5 **2.7.3 Loss of additional sink capacity**

6 The DGVM simulations now used to estimate S_{LAND} are carried out with a fixed preindustrial land-
7 cover. Hence, they overestimate the land sink by ignoring historical changes in vegetation cover
8 due to land use and how this affected the global terrestrial biosphere's capacity to remove CO₂
9 from the atmosphere. Historical land-cover change was dominated by transitions from vegetation
10 types that can provide a large sink per area unit (typically, forests) to others less efficient in
11 removing CO₂ from the atmosphere (typically, croplands). The resultant decrease in land sink,
12 called the 'loss of sink capacity', is calculated as the difference between the actual land sink under
13 changing land-cover and the counter-factual land sink under preindustrial land-cover.

14 Here, we provide a quantitative estimate of this term to be used in the discussion. Our estimate
15 uses the compact Earth system model OSCAR (Gasser et al., 2017) whose land carbon cycle
16 component is designed to emulate the behaviour of TRENDY and CMIP5 complex models. We use
17 OSCAR v2.2.1 (an update of v2.2 in which minor changes) in a probabilistic setup identical to the
18 one of Arneeth et al. (2017) but with a Monte Carlo ensemble of 2000 simulations. For each, we
19 calculate separately S_{LAND} and the loss of additional sink capacity. We then constrain the ensemble
20 by weighting each member to obtain a distribution of cumulative S_{LAND} over 1850-2005 close to
21 the DGVMs used here. From this ensemble, we estimate a loss of additional sink capacity of $0.4 \pm$
22 0.3 GtC yr^{-1} on average over 2005-2014, and by extrapolation of $20 \pm 15 \text{ GtC}$ accumulated
23 between 1870 and 2016.

24 **3 Results**

25 **3.1 Global carbon budget mean and variability for 1959 – 2016**

26 The global carbon budget averaged over the last half-century is shown in Fig. 3. For this time
27 period, 82% of the total emissions ($E_{\text{FF}} + E_{\text{LUC}}$) were caused by fossil fuels and industry, and 18% by
28 land-use change. The total emissions were partitioned among the atmosphere (45%), ocean (23%)
29 and land (32%). All components except land-use change emissions have grown since 1959, with

1 important interannual variability in the growth rate in atmospheric CO₂ concentration and in the
2 land CO₂ sink (Fig. 4), and some decadal variability in all terms (Table 7).

3 **3.1.1 CO₂ emissions**

4 Global CO₂ emissions from fossil fuels and industry have increased every decade from an average
5 of 3.1 ± 0.2 GtC yr⁻¹ in the 1960s to an average of 9.4 ± 0.5 GtC yr⁻¹ during 2007-2016 (Table 7 and
6 Fig. 5). The growth rate in these emissions decreased between the 1960s and the 1990s, from
7 4.5% yr⁻¹ in the 1960s (1960-1969), 2.8% yr⁻¹ in the 1970s (1970-1979), 1.9% yr⁻¹ in the 1980s
8 (1980-1989), and to 1.1% yr⁻¹ in the 1990s (1990-1999). After this period, the growth rate began
9 increasing again in the 2000s at an average growth rate of 3.3% yr⁻¹, decreasing to 1.8% yr⁻¹ for
10 the last decade (2007-2016), and to +0.4% yr⁻¹ during 2014-2016.

11 In contrast, CO₂ emissions from land-use change have remained relatively constant at around 1.3
12 ± 0.7 GtC yr⁻¹ over the past half-century, in agreement with the DGVM ensemble of models.
13 However, there is no agreement on the trend over the full period, with two bookkeeping models
14 suggesting opposite trends and no coherence among DGVMs (Fig. 6).

15 **3.1.2 Partitioning among the atmosphere, ocean and land**

16 The growth rate in atmospheric CO₂ level increased from 1.7 ± 0.1 GtC yr⁻¹ in the 1960s to $4.7 \pm$
17 0.1 GtC yr⁻¹ during 2007-2016 with important decadal variations (Table 7). Both ocean and land
18 CO₂ sinks increased roughly in line with the atmospheric increase, but with significant decadal
19 variability on land (Table 7), and possibly in the ocean (Fig. 7).

20 The ocean CO₂ sink increased from 1.0 ± 0.5 GtC yr⁻¹ in the 1960s to 2.4 ± 0.5 GtC yr⁻¹ during 2007-
21 2016, with interannual variations of the order of a few tenths of GtC yr⁻¹ generally showing an
22 increased ocean sink during large El Niño events (i.e. 1997-1998) (Fig. 7; Rödenbeck et al., 2014).
23 Note the lower ocean sink estimate compared to previous global carbon budget releases is due to
24 the fact that ocean models are no longer normalised to observations. Although there is some
25 coherence among the GOBMs and pCO₂-based flux products regarding the mean, there is poor
26 agreement for interannual variability and the ocean models underestimate decadal variability
27 (Sect. 2.4.3 and Fig. 7, also see new data-based decadal estimate of DeVries et al. (2017)).

28 The terrestrial CO₂ sink increased from 1.4 ± 0.7 GtC yr⁻¹ in the 1960s to 3.0 ± 0.8 GtC yr⁻¹ during
29 2007-2016, with important interannual variations of up to 2 GtC yr⁻¹ generally showing a

1 decreased land sink during El Niño events, overcompensating the increase in ocean sink and
2 responsible for the enhanced growth rate in atmospheric CO₂ concentration during El Niño events
3 (Fig. 6). The larger land CO₂ sink during 2007-2016 compared to the 1960s is reproduced by all the
4 DGVMs in response to combined atmospheric CO₂ increase, climate and variability, consistent
5 with constraints from the other budget terms (Table 6).

6 The total CO₂ fluxes on land ($S_{\text{LAND}} - E_{\text{LUC}}$) constrained by the atmospheric inversions show in
7 general very good agreement with the global budget estimate, as expected given the strong
8 constraints of G_{ATM} and the small relative uncertainty assumed on S_{OCEAN} and E_{FF} by inversions. The
9 total land flux is of similar magnitude for the decadal average, with estimates for 2007-2016 from
10 the three inversions of 1.8, 1.4 and 2.3 GtC yr⁻¹ compared to 1.7 ± 0.7 GtC yr⁻¹ from the DGVMs
11 and 2.3 ± 0.7 GtC yr⁻¹ for the total flux computed with the carbon budget constraints (Table 6).

12 3.1.3 Budget imbalance

13 The carbon budget imbalance (B_{IM} ; Eq. 1) quantifies the mismatch between the estimated total
14 emissions and the estimated changes in the atmosphere, land and ocean reservoirs. The mean
15 budget imbalance from 1959 to 2016 is very small (0.07 GtC yr⁻¹) and shows no trend over the full
16 time series. Although the process models (GOBMs and DGVMs) have been selected to match
17 observational constraints in the 1990s, they are independent of the estimated emissions from
18 fossil fuels and industry, and therefore the near-zero mean and trend in the budget imbalance is
19 an indirect evidence of a coherent community understanding of the emissions and their
20 partitioning on those time scales (Fig. 4). However, the budget imbalance shows substantial
21 variability of the order of ± 1 GtC yr⁻¹, particularly over semi-decadal time scales, although most of
22 the variability is within the uncertainty of the estimates. The imbalance during the 1960s, early
23 1990s, and in the last decade, suggest that either the emissions were overestimated or the sinks
24 were underestimated during these periods. The reverse is true for the 1970s and around 1995-
25 2000 (Fig. 3).

26 We cannot attribute the cause of the variability in the budget imbalance with our analysis, only to
27 note that the budget imbalance is unlikely to be explained by errors or biases in the emissions
28 alone because of its large semi-decadal variability component, a variability that is untypical of
29 emissions (Fig. 4). Errors in S_{LAND} and S_{OCEAN} are more likely to be the main cause for the budget
30 imbalance. For example, underestimation of the S_{LAND} by DGVMs has been reported following the

1 eruption of Mount Pinatubo in 1991 possibly due to missing responses to changes in diffuse
2 radiation (Mercado et al., 2009), and DGVMs are suspected to overestimate the land sink in
3 response to the wet decade of the 1970s (Sitch et al., 2003). Decadal and semi-decadal variability
4 in the ocean sink has been also reported recently (DeVries et al., 2017; Landschützer et al., 2015),
5 with the pCO₂-based ocean flux products suggesting a smaller than expected ocean CO₂ sink in the
6 1990s and a larger than expected sink in the 2000s (Fig. 7), possibly caused by changes in ocean
7 circulation (DeVries et al., 2017) not captured in coarse resolution GOBMs used here (Dufour et
8 al., 2013).

9 **3.1.4 Regional distribution**

10 Fig 8 shows the partitioning of the total surface fluxes excluding emissions from fossil fuels and
11 industry ($S_{\text{LAND}} + S_{\text{OCEAN}} - E_{\text{LUC}}$) according to the multi-model average of the process models in the
12 ocean and on land (GOBMs and DGVMs), and to the three atmospheric inversions. The total
13 surface fluxes provide information on the regional distribution of those fluxes by latitude bands
14 (Fig. 8). The global mean CO₂ fluxes from process models for 2007-2016 is $4.1 \pm 1.0 \text{ GtC yr}^{-1}$. This is
15 comparable to the fluxes of $4.6 \pm 0.5 \text{ GtC yr}^{-1}$ inferred from the remainder of the carbon budget
16 ($E_{\text{FF}} - G_{\text{ATM}}$ in Equation 1; Table 7) within their respective uncertainties. The total CO₂ fluxes from
17 the three inversions range between 4.1 and 5.0 GtC yr⁻¹, consistent with the carbon budget as
18 expected from the constraints on the inversions.

19 In the South (south of 30°S), the atmospheric inversions and process models all suggest a CO₂ sink
20 for 2007-2016 around 1.3-1.4 GtC yr⁻¹ (Fig. 8), although interannual to decadal variability is not
21 fully consistent across methods. The interannual variability in the South is low because of the
22 dominance of ocean area with low variability compared to land areas.

23 In the Tropics (30°S-30°N), both the atmospheric inversions and process models suggest the
24 carbon balance in this region is close to neutral on average over the past decade, with fluxes for
25 2007-2016 ranging between -0.5 and +0.5 GtC yr⁻¹. Both the process models and the inversions
26 consistently allocate more year-to-year variability of CO₂ fluxes to the Tropics compared to the
27 North (north of 30°N; Fig. 8), this variability being dominated by land fluxes.

28 In the North (north of 30°N), the inversions and process models are not in agreement on the
29 magnitude of the CO₂ sink, with the ensemble mean of the process models suggesting a total

1 northern hemisphere sink for 2007-2016 of $2.3 \pm 0.6 \text{ GtC yr}^{-1}$, below the estimates from the three
2 inversions that estimate a sink of 2.7, 3.0 and 4.1 GtC yr^{-1} (Fig. 8). The mean difference can only
3 partly be explained by the influence of river fluxes, which is seen by the inversions but not
4 included in the process models; this flux in the Northern Hemisphere would be less than 0.45 GtC
5 yr^{-1} because only the anthropogenic contribution to river fluxes needs to be accounted for. The
6 CTE and Jena CarboScope inversions are within the one standard deviation of the process models
7 for the mean sink during their overlap period, while the CAMS inversion gives a higher sink in the
8 North than the process models, and a correspondingly higher source in the Tropics.

9 Differences between CTE, CAMS, and Jena CarboScope may be related e.g. to differences in
10 interhemispheric mixing time of their transport models, and other inversion settings (Table 4c).
11 Separate analysis has shown that the influence of the chosen prior land and ocean fluxes is minor
12 compared to other aspects of each inversion. In comparison to the previous global carbon budget
13 publication, the fossil fuel inputs for CarboScope changed to lower emissions in the North
14 compared to CTE and CAMS, resulting in a smaller Northern sink for CarboScope compared to the
15 previous estimate. Differences between the mean fluxes of CAMS in the North and the ensemble
16 of process models cannot be simply explained. They could either reflect a bias in this inversion or
17 missing processes or biases in the process models, such as the lack of adequate parameterizations
18 for forest management in the North and for forest degradation emissions in Tropics for the
19 DGVMs. The estimated contribution of the North and its uncertainty from process models is
20 sensitive both to the ensemble of process models used and to the specifics of each inversion.

21 **3.2 Global carbon budget for the last decade (2007 – 2016)**

22 The global carbon budget averaged over the last decade (2007-2016) is shown in Fig. 2. For this
23 time period, 88% of the total emissions ($E_{\text{FF}} + E_{\text{LUC}}$) were from fossil fuels and industry (E_{FF}), and
24 12% from land-use change (E_{LUC}). The total emissions were partitioned among the atmosphere
25 (44%), ocean (22%) and land (28%), with a remaining unattributed budget imbalance (5%).

26 **3.2.1 CO₂ emissions**

27 Global CO₂ emissions from fossil fuels and industry grew at a rate of $1.8\% \text{ yr}^{-1}$ for the last decade
28 (2007-2016), slowing down to $+0.4\% \text{ yr}^{-1}$ during 2014-2016. China's emissions increased by $+3.8\%$
29 yr^{-1} on average (increasing by $+1.7 \text{ GtC yr}^{-1}$ during the 10-year period) dominating the global

1 trends, followed by India's emissions increase by $+5.8\% \text{ yr}^{-1}$ (increasing by $+0.30 \text{ GtC yr}^{-1}$), while
2 emissions decreased in EU28 by $2.2\% \text{ yr}^{-1}$ (decreasing by $-0.23 \text{ GtC yr}^{-1}$), and in the USA by $1.0\% \text{ yr}^{-1}$
3 ¹ (decreasing by $-0.19 \text{ GtC yr}^{-1}$). In the past decade, emissions from fossil fuels and industry
4 decreased significantly (at the 95% level) in 26 countries. 22 of these countries had positive
5 growth in GDP over the same time period, representing 20% of global emissions (Austria, Belgium,
6 Bulgaria, Czech Republic, Denmark, France, Hungary, Ireland, Latvia, Lithuania, Luxembourg,
7 Macedonia, Malta, Netherlands, Poland, Romania, Serbia, Slovakia, Sweden, Switzerland, United
8 Kingdom, USA).

9 In contrast, there is no apparent trend in CO_2 emissions from land-use change (Fig. 6), though the
10 data is very uncertain.

11 **3.2.2 Partitioning among the atmosphere, ocean and land**

12 The growth rate in atmospheric CO_2 concentration was initially constant and then increased
13 during the later part of the decade 2007-2016, reflecting a similar constant level followed by a
14 decrease in the land sink, albeit with large interannual variability (Fig. 4). During the same period,
15 the ocean CO_2 sink appears to have intensified, an effect which is particularly apparent in the
16 pCO_2 -based flux products (Fig. 7) and is thought to originate at least in part in the Southern Ocean
17 (Landschützer et al., 2015).

18 **3.2.3 Budget imbalance**

19 The budget imbalance was 0.6 GtC yr^{-1} on average over 2007-2016. Although the uncertainties are
20 large in each term, the sustained imbalance over a decade suggests an overestimation of the
21 emissions and/or an underestimation of the sinks. Such a large imbalance is unlikely to originate
22 from the emissions alone because it would indicate sustained bias in emissions over a 10-year
23 period that is as large as the 1-sigma uncertainty. An origin in the land and/or ocean sink is more
24 likely, given the large variability of the land sink and the suspected underestimation of decadal
25 variability in the ocean sink.

1 **3.3 Global carbon budget for year 2016**

2 **3.3.1 CO₂ emissions**

3 Preliminary global CO₂ emissions from fossil fuels and industry based on BP energy statistics are
4 for emissions remaining nearly constant between 2015 and 2016 at 9.9 ± 0.5 GtC in 2016 (Fig. 5),
5 distributed among coal (40%), oil (34%), gas (19%), cement (5.6%) and gas flaring (0.7%).
6 Compared to the previous year, emissions from coal decreased by -1.7% , while emissions from
7 oil, gas, and cement increased by 1.5% , 1.5% , and 1.0% , respectively. All growth rates presented
8 are adjusted for leap year, unless stated otherwise.

9 Emissions in 2016 were 0.2% higher than in 2015, continuing the low growth trends observed in
10 2014 and 2015. This growth rate is as projected in Le Quéré et al. (2016) based on national
11 emissions projections for China and the USA, and projections of gross domestic product corrected
12 for I_{FF} trends for the rest of the world. The specific projection for 2016 for China made last year of
13 -0.5% (range of -3.8% to $+1.3\%$) is very close to the realised growth rate of -0.3% . Similarly, the
14 projected growth for the US of -1.7% (range of -4.0% to $+0.6\%$) is very close to the realised
15 growth rate of -2.1% , and the projected growth for the rest of the world (ROW) of $+1.0\%$ (range
16 of -0.4% to 2.5%) matches the realised rate of 1.3% .

17 In 2016, the largest absolute contributions to global CO₂ emissions were from China (28%), the
18 USA (15%), the EU (28 member states; 10%), and India (6.7%). The percentages are the fraction of
19 the global emissions including bunker fuels (3.1%). These four regions account for 59% of global
20 CO₂ emissions. Growth rates for these countries from 2015 to 2016 were -0.3% (China), -2.1%
21 (USA), -0.3% (EU28), and $+4.5\%$ (India). The per-capita CO₂ emissions in 2016 were 1.1 tC person⁻¹
22 yr⁻¹ for the globe, and were 4.5 (USA), 2.0 (China), 1.9 (EU28) and 0.5 (India) tC person⁻¹ yr⁻¹ for the
23 four highest emitting countries (Fig. 5e).

24 Territorial emissions in Annex B countries (developed countries as per the Kyoto Protocol which
25 initially had binding mitigation targets) decreased by -0.2% yr⁻¹ on average during 1990-2015.
26 Trends observed for consumption emissions were less monotonic, with 0.7% yr⁻¹ growth over
27 1990-2007 and a -1.2% yr⁻¹ decrease over 2007-2015 (Fig. 5c). In non-Annex B countries
28 (emerging economies and less developed countries as per the Kyoto Protocol with no binding
29 mitigation commitments) territorial emissions grew at 4.6% yr⁻¹ during 1990-2015, while
30 consumption emissions grew at 4.5% yr⁻¹. In 1990, 65% of global territorial emissions were

1 emitted in Annex B countries (32% in non-Annex B, and 2% in bunker fuels used for international
2 shipping and aviation), while in 2015 this had reduced to 37% (60% in non-Annex B, and 3% in
3 bunker fuels). For consumption emissions, this split was 68% in 1990 and 42% in 2015 (32% to
4 58% in non-Annex B). The difference between territorial and consumption emissions (the net
5 emission transfer via international trade) from non-Annex B to Annex B countries has increased
6 from near zero in 1990 to 0.3 GtC yr^{-1} around 2005 and remained relatively stable afterwards until
7 the last year available (2015; Fig. 5). The increase in net emission transfers of 0.28 GtC yr^{-1}
8 between 1990 and 2015 compares with the emission reduction of 0.5 GtC yr^{-1} in Annex B
9 countries. These results show the importance of net emission transfer via international trade from
10 non-Annex B to Annex B countries, and the stabilisation of emissions transfer when averaged over
11 Annex B countries during the past decade. In 2015, the biggest emitters from a consumption
12 perspective were China (23% of the global total), USA (16%), EU28 (12%), and India (6%).
13 The global CO_2 emissions from land-use change are estimated as $1.3 \pm 0.5 \text{ GtC}$ in 2016, as for the
14 previous decade but with low confidence in the annual change.

15 **3.3.2 Partitioning among the atmosphere, ocean and land**

16 The growth rate in atmospheric CO_2 concentration was $6.1 \pm 0.2 \text{ GtC}$ in 2016 ($2.89 \pm 0.09 \text{ ppm}$; Fig.
17 4; Dlugokencky and Tans, 2017). This is well above the 2007-2016 average of $4.7 \pm 0.1 \text{ GtC yr}^{-1}$ and
18 reflects the large interannual variability in the growth rate of atmospheric CO_2 concentration
19 associated with El Niño and La Niña events.

20 The estimated ocean CO_2 sink was $2.6 \pm 0.5 \text{ GtC yr}^{-1}$ in 2016, only marginally above 2015 according
21 to the average of the ocean models but with large differences among estimates (Fig. 7).

22 The terrestrial CO_2 sink from the model ensemble was $2.7 \pm 1.0 \text{ GtC}$ in 2016, near the decadal
23 average (Fig. 4) and consistent with constraints from the rest of the budget (Table 6).

24 The budget imbalance was -0.3 GtC in 2016, indicating a small overestimation of the emissions
25 and/or underestimation of the sink for that year, with large uncertainties.

26 **3.4 Global carbon budget projection for year 2017**

27 **3.4.1 CO_2 emissions**

28 Emissions from fossil fuels and industry (E_{FF}) for 2017 are projected to increase by +2.0% (range of
29 0.8% to +3.0%; Table 8; (Jackson et al., 2017; Peters et al., 2017)). Our method contains several

1 assumptions that could influence the estimate beyond the given range, and as such, it has an
2 indicative value only. Within the given assumptions, global emissions would increase to 10.0 ± 0.5
3 GtC (36.8 ± 1.8 GtCO₂) in 2017.

4 For China, the expected change based on available data as of 19 September 2017 (see Sect. 2.1.4)
5 is for an increase in emissions of +3.5% (range of +0.7% to +5.4%) in 2017 compared to 2016. This
6 is based on estimated growth in coal (+3%; the main fuel source in China), oil (+5.0%) and natural
7 gas (+11.7%) consumption and a decline in cement production (−0.5%). The uncertainty range
8 considers the spread between different data sources, and variances of typical revisions of Chinese
9 data over time. The uncertainty in the growth rate of coal consumption also reflects uncertainty in
10 the evolution of energy density and carbon content of coal.

11 For the USA, the EIA emissions projection for 2017 combined with cement data from USGS gives a
12 decrease of −0.4 % (range of −2.7 to +1.9 %) compared to 2016.

13 For India, our projection for 2017 gives an increase of +2.0% (range of 0.2% to +3.8%) over 2016.

14 For the rest of the world (including EU28), the expected growth for 2017 is +1.9% (range of 0.3%
15 to +3.4%). This is computed using the GDP projection for the world excluding China, USA, and
16 India of 3.0% made by the IMF (IMF, 2017) and a decrease in I_{FF} of $-1.1\% \text{ yr}^{-1}$ which is the average
17 from 2007-2016. The uncertainty range is based on the standard deviation of the interannual
18 variability in I_{FF} during 2007-2016 of $\pm 1.0\% \text{ yr}^{-1}$ and our estimate of uncertainty in the IMF's GDP
19 forecast of $\pm 0.5\%$. Applying the method to the EU28 individually would give a projection of −0.2%
20 (range of −2.0% to +1.6%) for EU28 and +2.3% (range of +0.5% to +4.0%) for the remaining
21 countries, though the uncertainties grow with the level of disaggregation.

22 Emissions from land-use change (E_{LUC}) for 2017 are projected to remain in line with or slightly
23 lower than their 2016 level of 1.3 GtC, based on active fire detections by October.

24 **3.4.2 Partitioning among the atmosphere, ocean and land**

25 The 2017 growth in atmospheric CO₂ concentration (G_{ATM}) is projected to be 5.3 GtC with
26 uncertainty around ± 1 GtC (2.5 ± 0.5 ppm). Combining projected E_{FF} , E_{LUC} and G_{ATM} suggests a
27 combined land and ocean sink ($S_{LAND} + S_{OCEAN}$) of about 6 GtC for 2017. Although each term has
28 large uncertainty, the oceanic sink S_{OCEAN} has generally low interannual variability and is likely to
29 remain close to its 2016 value of around 2.6 GtC, leaving a rough estimated land sink S_{LAND} of

1 around 3.4 GtC, near its decadal average (Table 6). This behaviour of the sink is expected due to
2 the El Niño-neutral conditions that prevailed during 2017, in stark contrast to the strong El Niño
3 conditions in 2015 and 2016 that reduced the land sink.

4 **3.5 Cumulative sources and sinks**

5 Cumulative historical sources and sinks have been revised compared to the previous global carbon
6 budgets. This version of the global carbon budget uses two updated bookkeeping models instead
7 of one bookkeeping model only, uses two ocean sink data-products instead of one data-product
8 only, and uses multiple DGVMs for the land sink instead of deriving the land sink from the residual
9 of the other terms. As a result of these methodological changes, the cumulative emissions and
10 their partitioning is significantly larger (by about 50 GtC) than our previous estimates. This large
11 difference highlights the uncertainty in reconstructing historical emission sources and sinks, and
12 this is noted through the large uncertainty associated with each term.

13 Cumulative fossil fuel and industry emissions for 1870–2016 were 420 ± 20 GtC for E_{FF} and, with
14 the revised bookkeeping models, 180 ± 60 GtC for E_{LUC} (Table 9), for a total of 600 ± 65 GtC. The
15 cumulative emissions from E_{LUC} are particularly uncertain, with large spread among individual
16 estimates of 135 GtC (Houghton) and 225 GtC (BLUE) for the two bookkeeping models and a range
17 of 70 to 230 GtC for the twelve DGVMs. These estimates are consistent with indirect constraints
18 from biomass observations (Li et al., 2017), but given the large spread a best estimate is difficult
19 to ascertain.

20 With the revised methodology, emissions were partitioned among the atmosphere (245 ± 5 GtC),
21 ocean (145 ± 20 GtC), and the land (185 ± 55 GtC). The use of nearly independent estimates for
22 the individual terms shows a cumulative budget imbalance of 20 GtC during 1870–2016, which, if
23 correct, suggests emissions are too high by the same proportion or the land or ocean sinks are
24 underestimated. The imbalance originates largely from the large E_{LUC} during the mid 1920s and
25 the mid 1960s which is unmatched by a growth in atmospheric CO_2 concentration as recorded in
26 ice cores (Fig. 3). The known loss of additional sink capacity of about 15 GtC due to reduced forest
27 cover has not been accounted in our method and further exacerbates the budget imbalance
28 (Section 2.7.3).

1 Cumulative emissions through to year 2017 increase to 610 ± 65 GtC (2235 ± 240 GtCO₂), with
2 about 70% contribution from E_{FF} and about 30% contribution from E_{LUC} . Cumulative emissions and
3 their partitioning for different periods are provided in Table 9.

4 Given the large revision in cumulative emissions, and its persistent uncertainties, we suggest
5 extreme caution is needed if using our updated cumulative emission estimate to determine the
6 “remaining carbon budget” to stay below given temperature limit (Rogelj et al., 2016). We suggest
7 estimating the remaining carbon budget by integrating scenario data from the current time to
8 some time in the future as proposed recently (Millar et al., 2017).

9 **4 Discussion**

10 Each year when the global carbon budget is published, each component for all previous years is
11 updated to take into account corrections that are the result of further scrutiny and verification of
12 the underlying data in the primary input data sets. The updates have generally been relatively
13 small (Fig. 9). However this year, we introduced a major methodological change to assess both
14 S_{OCEAN} and S_{LAND} directly using multiple process models constrained by observations, and to keep
15 track of the budget imbalance separately. We also use multiple bookkeeping estimates for E_{LUC} .
16 Therefore, the update compared to previous years has led to more substantial revisions,
17 particularly concerning the mean S_{OCEAN} , the variability of S_{LAND} , and the trends in E_{LUC} (Fig. 9).

18 The budget imbalance provides a measure of the limitations in observations, in understanding or
19 full representation of processes in models, and/or in the integration of the carbon budget
20 components. The mean global budget imbalance is close to zero and there is no trend over the
21 entire time period (Fig. 4). However, the budget imbalance reaches as much as ± 2 GtC yr⁻¹ in
22 individual years, and ± 0.6 GtC yr⁻¹ in individual decades (Table 7). Such large budget imbalance
23 limits our ability to verify reported emissions and limits our confidence in the underlying
24 processes regulating the carbon cycle feedbacks with climate change (Peters et al., 2017).

25 Another semi-independent way to evaluate the carbon budget results is provided through the use
26 of atmospheric and oceanic CO₂ data in data-products (atmospheric inversions and pCO₂-based
27 ocean flux products). The comparison shows a first-order consistency between pCO₂-based data-
28 products and process models but with substantial discrepancies, particularly for the allocation of
29 the mean surface fluxes between the tropics and the Northern hemisphere, and for highlighting
30 underestimated decadal variability in S_{OCEAN} . Understanding the causes of these discrepancies and

1 further analysis of regional carbon budgets would provide additional information to quantify and
2 improve our estimates, as has been shown by the project REgional Carbon Cycle Assessment and
3 Processes (RECCAP; Canadell et al., 2012-2013).

4 To help improve the Global Carbon Budget components, we provide a list of the major known
5 uncertainties for each component, defined as those uncertainties that have been a demonstrated
6 effect of at least 0.3 GtC yr^{-1} (Table 10). We identified multiple sources of uncertainties for E_{LUC} ,
7 including in the land-cover and land-use change statistics, representation of management
8 processes, and methodologies. There are also multiple sources of uncertainties in S_{LAND} , mostly
9 related to the understanding and representation of processes, and in S_{OCEAN} , particularly related to
10 representing the effects of variable ocean circulation in models as highlighted by recent
11 observations. Finally, the quality of the energy statistics and of the emissions factors are largest
12 sources of uncertainties for E_{FF} . There are no demonstrated uncertainties in G_{ATM} larger than 0.3
13 GtC yr^{-1} , although the conversion of the growth rate into a global annual flux assuming
14 instantaneous mixing throughout the atmosphere introduces additional errors that have not yet
15 been quantified. Multiple other sources of uncertainties have been identified (i.e. in cement
16 emissions) that could add up to significant contributions but are unlikely to be the main sources of
17 the budget imbalance.

18 There are many more uncertainties affecting the annual estimates compared to the mean and
19 trend, some of which could be improved with better data. Of the various terms in the global
20 budget, only the emissions from fossil fuels and industry and the growth rate in atmospheric CO_2
21 concentration are based primarily on empirical inputs supporting annual estimates in this carbon
22 budget. $p\text{CO}_2$ -based flux products for the ocean CO_2 sink provide new ways to evaluate the model
23 results, but there are still large discrepancies among estimates. Given the growing reliance on
24 process models and $p\text{CO}_2$ -based flux products in our Global Carbon Budget, it is critical that data-
25 based metrics are developed and used to inform the selection of models and the improvement of
26 their process representation in the long term.

27 **5 Data availability**

28 The data presented here are made available in the belief that their wide dissemination will lead to
29 greater understanding and new scientific insights of how the carbon cycle works, how humans are
30 altering it, and how we can mitigate the resulting human-driven climate change. The free

1 availability of these data does not constitute permission for publication of the data. For research
2 projects, if the data are essential to the work, or if an important result or conclusion depends on
3 the data, co-authorship may need to be considered. Full contact details and information on how
4 to cite the data are given at the top of each page in the accompanying database, and summarised
5 in Table 2.

6 The accompanying database includes two Excel files organised in the following spreadsheets
7 (accessible with the free viewer <http://www.microsoft.com/en-us/download/details.aspx?id=10>):

8 File Global_Carbon_Budget_2017v1.0.xlsx includes the following:

- 9 1. Summary
- 10 2. The global carbon budget (1959-2016);
- 11 3. Global CO₂ emissions from fossil fuels and cement production by fuel type, and the per-capita
12 emissions (1959-2016);
- 13 4. CO₂ emissions from land-use change from the individual methods and models (1959-2016);
- 14 5. Ocean CO₂ sink from the individual ocean models and pCO₂-based products (1959-2016);
- 15 6. Terrestrial CO₂ sink from the DGVMs (1959-2016);
- 16 7. Additional information on the carbon balance prior to 1959 (1750-2016).

17 File National_Carbon_Emissions_2017v1.0.xlsx includes the following:

- 18 1. Summary
- 19 2. Territorial country CO₂ emissions from fossil fuels and industry (1959-2016) from CDIAC,
20 extended to 2016 using BP data;
- 21 3. Territorial country CO₂ emissions from fossil fuels and industry (1959-2016) from CDIAC with
22 UNFCCC data overwritten where available, extended to 2016 using BP data;
- 23 4. Consumption country CO₂ emissions from fossil fuels and industry and emissions transfer
24 from the international trade of goods and services (1990-2015) using CDIAC/UNFCCC data
25 (worksheet 3 above) as reference;
- 26 5. Emissions transfers (Consumption minus territorial emissions; 1990-2015);
- 27 6. Country definitions;
- 28 7. Details of disaggregated countries;
- 29 8. Details of aggregated countries.

30 National emissions data are also available from the Global Carbon Atlas (globalcarbonatlas.org).

6 Conclusions

The estimation of global CO₂ emissions and sinks is a major effort by the carbon cycle research community that requires a combination of measurements and compilation of statistical estimates and results from models. The delivery of an annual carbon budget serves two purposes. First, there is a large demand for up-to-date information on the state of the anthropogenic perturbation of the climate system and its underpinning causes. A broad stakeholder community relies on the data sets associated with the annual carbon budget including scientists, policy makers, businesses, journalists, and the broader society increasingly engaged in adapting to and mitigating human-driven climate change. Second, over the last decade we have seen unprecedented changes in the human and biophysical environments (e.g. changes in the growth of fossil fuel emissions, ocean temperatures, and strength of the sink), which call for more frequent assessments of the state of the planet, and by implication, a better understanding of the future evolution of the carbon cycle. Both the ocean and the land surface presently remove a large fraction of anthropogenic emissions. Any significant change in the function of carbon sinks is of great importance to climate policymaking, as they affect the excess CO₂ remaining in the atmosphere and therefore the compatible emissions for any climate stabilisation target. Better constraints of carbon cycle models against contemporary data sets raise the capacity for the models to become more accurate at future projections. This all requires more frequent, robust, and transparent data sets and methods that can be scrutinized and replicated. This paper via ‘living data’ will help to keep track of new budget updates.

Acknowledgments. We thank all people and institutions who provided the data used in this carbon budget; C. Enright, W. Peters, and S. Shu for their involvement in the development, use and analysis of the models and data-products used here; F. Joos, S. Khatiwala and T. DeVries for providing historical data; and A. Kirk for technical support. We thank E. Dlugokencky who provided the atmospheric CO₂ measurements used here; C. Landa, C. Bernard and S. Jones of the Bjerknes Climate Data Centre and the ICOS Ocean Thematic Centre data management at the University of Bergen, who helped with gathering information from the SOCAT community, and all those involved in collecting and providing oceanographic CO₂ measurements used here, in particular for the new ocean data for year 2016 (see Table A2). This is NOAA-PMEL contribution number 4728. We thank the institutions and funding agencies responsible for the collection and quality control of the data included in SOCAT, and the support of the International Ocean Carbon Coordination

1 Project (IOCCP), the Surface Ocean Lower Atmosphere Study (SOLAS), and the Integrated Marine
2 Biogeochemistry, Ecosystem Research (IMBER) programme. Long-term support for the CRU TS
3 dataset is currently provided by the UK National Centre for Atmospheric Science (NCAS), a NERC
4 collaborative centre.

5 Finally, we thank all funders who have supported the individual and joint contributions to this
6 work (see Appendix Table A1), as well as M. Heimann, H. Dolman, and the many researchers who
7 have provided feedback during the GCP community consultation held at the 10th International CO₂
8 Conference in Interlaken, Switzerland.

 5

6 Tables

7 **Table 1.** Factors used to convert carbon in various units (by convention, Unit 1 = Unit 2
 8 conversion).

Unit 1	Unit 2	Conversion	Source
GtC (gigatonnes of carbon)	ppm (parts per million) ^a	2.12 ^b	Ballantyne et al. (2012)
GtC (gigatonnes of carbon)	PgC (petagrams of carbon)	1	SI unit conversion
GtCO ₂ (gigatonnes of carbon dioxide)	GtC (gigatonnes of carbon)	3.664	44.01/12.011 in mass equivalent
GtC (gigatonnes of carbon)	MtC (megatonnes of carbon)	1000	SI unit conversion

9 ^aMeasurements of atmospheric CO₂ concentration have units of dry-air mole fraction. ‘ppm’ is an
 10 abbreviation for micromole/mol, dry air.
 11 ^bThe use of a factor of 2.12 assumes that all the atmosphere is well mixed within one year. In reality, only
 12 the troposphere is well mixed and the growth rate of CO₂ concentration in the less well-mixed stratosphere
 13 is not measured by sites from the NOAA network. Using a factor of 2.12 makes the approximation that the
 14 growth rate of CO₂ concentration in the stratosphere equals that of the troposphere on a yearly basis.
 15

1 **Table 2.** How to cite the individual components of the global carbon budget presented here.

Component	Primary reference
Global emissions from fossil fuels and industry (E_{FF}), total and by fuel type	Boden et al., (2017)
National territorial emissions from fossil fuels and industry (E_{FF})	CDIAC source: Boden et al., (2017) UNFCCC (2017)
National consumption-based emissions from fossil fuels and industry (E_{FF}) by country (consumption)	Peters et al. (2011b) updated as described in this paper
Land-use change emissions (E_{LUC})	average from Houghton and Nassikas (2017) and Hansis et al., (2015), both updated as described in this paper
Growth rate in atmospheric CO_2 concentration (G_{ATM})	Dlugokencky and Tans (2017)
Ocean and land CO_2 sinks (S_{OCEAN} and S_{LAND})	This paper for S_{OCEAN} and S_{LAND} and references in Table 5 for individual models.

Table 3. Main methodological changes in the global carbon budget since first publication. Unless specified below, the methodology was identical to that described in the current paper. Furthermore, methodological changes introduced in one year are kept for the following years unless noted. Empty cells mean there were no methodological changes introduced that year.

Publication year ^a	Global	Fossil fuel emissions Country (territorial)	Country (consumption)	LUC emissions	Atmosphere	Reservoirs Ocean	Land	Uncertainty & other changes
2006		Split in regions						
Raupach et al. (2007)				E_{LUC} based on FAO-FRA 2005; constant E_{LUC} for 2006	1959-1979 data from Mauna Loa; data after 1980 from global average	Based on one ocean model tuned to reproduced observed 1990s sink		±1σ provided for all components
Canadell et al. (2007)				Constant E_{LUC} for 2007				
2008 (online)				Fire-based emission anomalies used for 2006-2008		Based on four ocean models normalised to observations with constant delta	First use of five DGVMs to compare with budget residual	
2009		Split between Annex B and non-Annex B	Results from an independent study discussed					
Le Quéré et al. (2009)				E_{LUC} updated with FAO-FRA 2010				
2010 Friedlingstein et al. (2010)		Emissions for top emitters						
2011			Split between Annex B and non-Annex B					
Peters et al. (2012b)		129 countries from 1959	129 countries and regions from 1990-2010 based on GTP8.0	E_{LUC} for 1997-2011 includes interannual anomalies from fire-based emissions	All years from global average	Based on 5 ocean models normalised to observations with ratio	Ten DGVMs available for S_{Land} ; First use of four models to compare with E_{LUC}	
Le Quéré et al. (2013)				E_{LUC} for 2012 estimated from 2001-2010 average		Based on six models compared with two data-products to year 2011	Coordinated DGVM experiments for S_{Land} and E_{LUC}	Confidence levels; cumulative emissions; budget from 1750
Peters et al. (2013)								
2013		250 countries ^b	134 countries and regions 1990-2011 based on GTP8.1, with detailed estimates for years 1997, 2001, 2004, and 2007	E_{LUC} for 1997-2013 includes interannual anomalies from fire-based emissions		Based on seven models	Based on ten models	Inclusion of breakdown of the sinks in three latitude bands and comparison with three atmospheric inversions
Le Quéré et al. (2014)								
2014		Three years of BP data	Three years of BP data					
Le Quéré et al. (2015b)								
2015		Projection for current year based Jan-Aug data	National emissions from UNFCCC extended to 2014 also provided	Detailed estimates introduced for 2011 based on GTP9		Based on eight models	Based on ten models with assessment of minimum realism	The decadal uncertainty for the DGVM ensemble mean now uses ±1σ of the decadal spread across models
Jackson et al. (2016)								Discussion of projection for full budget for current year
2016		Two years of BP data	Added three small countries; CHN emissions from 1990 from BP data (this release only)	Preliminary E_{LUC} using FRA-2015 shown for comparison; use of five DGVMs		Based on seven models	Based on fourteen models	
Le Quéré et al. (2016)								
2017 (this study)		Projection includes India-specific data		Average of two bookkeeping models; use of twelve DGVMs		Based on eight models that match the observed sink for the 1990s; no longer normalised	Based on fifteen models that meet three criteria (see Sect. 2.5)	Land multi-model average now used in main carbon budget; with the carbon imbalance presented separately; new table of key uncertainties

- 1 ^aThe naming convention of the budgets has changed. Up to and including 2010, the budget year (Carbon Budget 2010) represented the latest year of the data. From 2012,
- 2 the budget year (Carbon Budget 2012) refers to the initial publication year.
- 3 ^bThe CDIAC database has about 250 countries, but we show data for 219 countries since we aggregate and disaggregate some countries to be consistent with current
- 4 country definitions (see Sect. 2.1.1 for more details).

Table 4a. Comparison of the processes included (Y) or not (N) in the bookkeeping and Dynamic Global Vegetation Models for their estimates of E_{LUC} and S_{LAND} . See Table 5 for model references. All models include deforestation and forest regrowth after abandonment of agriculture (or from afforestation activities on agricultural land).

Processes relevant also for S _{LAND}																	
Fire simulation	US only	N	N	Y	Y	Y	N	Y	N	Y	Y	Y	N	N	Y	Y	Y
Climate and variability	N	N	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
CO ₂ fertilisation	N ^e	N ^e	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Carbon-nitrogen interactions, including N deposition	N ⁱ	N ⁱ	Y	N ^e	Y	Y	Y	N	N	Y	N	Y	Y	N ^e	N	Y ^c	N

^a Refers to the routine harvest of established managed forests rather than pools of harvested products.

^b No back- and forth-transitions between vegetation types at the country-level, but if forest loss based on FRA exceeded agricultural expansion based on FAO, then this amount of area

^c Limited. Nitrogen uptake is simulated as a function of soil C, and Vcmax is an empirical function of canopy N. Does not consider N deposition.

^d Available but not active for comparability between the two LU forcings.

^e Although C-N cycle interactions are not represented, the model includes a parameterization of down-regulation of photosynthesis as CO₂ increases to emulate nutrient constraints (Arora et al., 2009)

^f Tillage is represented over croplands by increased soil carbon decomposition rate and reduced humification of litter to soil carbon.

^g Bookkeeping models include effect of CO₂-fertilization as captured by observed carbon densities, but not as an effect transient in time.

^h 20% reduction of active SOC pool turnover time for C3 crop and 40% reduction for C4 crops

ⁱ Process captured implicitly by use of observed carbon densities.

^j Three DGVMs were excluded from the E_{LUC} estimate due to an initial peak of E_{LUC} emissions caused by a cold start of shifting cultivation in 1860.

Table 5. References for the process models, pCO₂-based ocean flux products, and atmospheric inversions included in Figs. 6-8. All models and products are updated with new data to end of year 2016.

Model/data name	Reference	Change from Le Quéré et al. (2016)
<i>Bookkeeping models for land-use change emissions</i>		
BLUE	Hansis et al. (2015)	Not applicable (not used in previous carbon budgets)
H&N	Houghton and Nassikas (2017)	updated from Houghton et al. (2012); key differences include Revised land-use change data to FAO2015, revised vegetation carbon densities, Indonesian and Malaysian peat burning and drainage added, removal of shifting cultivation
<i>Dynamic global vegetation models</i>		
CABLE	Haverd et al., (2017)	Optimisation of plant investment in Rubisco- vs electron transport-limited photosynthesis; temperature-dependent onset of spring recovery in evergreen needle-leaves
CLASS-CTEM	Melton and Arora (2016)	A soil colour index is now used to determine soil albedo as opposed to soil texture. Soil albedo still gets modulated by other factors including soil moisture.
CLM4.5(BGC)	Oleson et al. (2013)	No change
DLEM	Tian et al. (2015)	Consideration of the expansion of cropland and pasture, compared with no pasture expansion in previous version.

* Estimates are corrected for the preindustrial influence of river fluxes (Sect. 2.7.2). See Tables 4c & 5 for references.

Table 7. Decadal mean in the five components of the anthropogenic CO₂ budget for different periods, and last year available. All values are in GtC yr⁻¹, and uncertainties are reported as ±1σ. Unlike previous versions of the Global Carbon Budget, the terrestrial sink (S_{LAND}) is now estimated independently from the mean of DGVM models. Therefore the table also shows the budget imbalance (B_{IM}), which provides a measure of the discrepancies among the nearly independent estimates and has an uncertainty exceeding ± 1 GtC yr⁻¹. A positive imbalance means the emissions are overestimated and/or the sinks are too small.

Mean (GtC yr ⁻¹)							
	1960-1969	1970-1979	1980-1989	1990-1999	2000-2009	2007-2016	2016

2 **Table 9.** Cumulative CO₂ emissions for different time periods in gigatonnes of carbon (GtC). All
 3 uncertainties are reported as $\pm 1\sigma$. E_{LUC} and S_{OCEAN} have been revised to incorporate multiple
 4 estimates (Section 3.5), and unlike previous versions of the Global Carbon Budget, the terrestrial
 5 sink (S_{LAND}) is now estimated independently from the mean of the DGVM. Therefore the table
 6 also shows the budget imbalance, which provides a measure of the discrepancies among the
 7 nearly independent estimates. Its uncertainty exceeds ± 60 GtC. The method used here does not
 8 capture the loss of additional sink capacity from reduced forest cover, which is about 15 GtC and
 9 would exacerbate the budget imbalance (see Section 2.7.3). All values are rounded to the
 10 nearest 5 GtC and therefore columns do not necessarily add to zero.

	Units of GtC	1750-2016	1850-2005	1959-2016	1870-2016	1870-2017 ^a
<i>Emissions</i>						
Fossil fuels and industry (E_{FF})		420 \pm 20	320 \pm 15	345 \pm 15	420 \pm 20	430 \pm 20
Land-use change emissions (E_{LUC})		225 \pm 75	180 \pm 60	75 \pm 40	180 \pm 60	180 \pm 60
Total emissions		645 \pm 80	500 \pm 60	415 \pm 45	600 \pm 65	610 \pm 65
<i>Partitioning</i>						
Growth rate in atmospheric CO ₂ concentration (G_{ATM}) ^b		270 \pm 5	200 \pm 5	185 \pm 5	245 \pm 5	250 \pm 5
Ocean sink (S_{OCEAN})		160 \pm 20	145 \pm 20	95 \pm 20	145 \pm 20	150 \pm 20
Terrestrial sink (S_{LAND}) ^c		205 \pm 55	155 \pm 45	135 \pm 35	190 \pm 45	190 \pm 55
<i>Budget imbalance</i>						
$B_{IM} = E_{FF} + E_{LUC} - (G_{ATM} + S_{OCEAN} + S_{LAND})$		(15)	(0)	(0)	(20)	(20)

11 ^aUsing projections for year 2017 (Sect. 3.3).

12 ^bA small change was introduced from Le Quéré et al. (2016) to be consistent with the annual analysis, whereby the
 13 growth in atmospheric CO₂ concentration is calculated from the difference between concentrations at the end of the
 14 year (deseasonalised), rather than averaged over the year.

15 ^cAssuming S_{LAND} increases proportionally to G_{ATM} prior to 1860 when the DGVM estimates start.

16

Table 10. Major known sources of uncertainties in each component of the Global Carbon Budget, defined as input data or processes that have a demonstrated effect of at least 0.3 GtC yr⁻¹.

Source of uncertainty	Time scale (years)	Location	Status	Evidence
Emissions from fossil fuels and industry (E_{FF} ; Section 2.1)				
energy statistics	annual to decadal	mainly China	see Sect. 2.1	(Korsbakken et al., 2016)
carbon content of coal	decadal	mainly China	see Sect. 2.1	(Liu et al., 2015)
Emissions from land-use change (E_{LUC} ; section 2.2)				
land-cover and land-use change statistics	continuous	global	see Sect. 2.2	(Houghton et al., 2012)
sub-grid-scale transitions	annual to decadal	global; in particular tropics	see Table 5	(Wilkenskjeld et al., 2014)
vegetation biomass	annual to decadal	global; in particular tropics	see Table 5	(Houghton et al., 2012)
wood and crop harvest	annual to decadal	global	see Table 5	(Arneeth et al., 2017)
peat burning ^a	multi-decadal trend	global; SE Asia	see Table 5	(van der Werf et al., 2010)
loss of additional sink capacity	multi-decadal trend	global	not included; Section 2.7.3	(Gitz and Ciais, 2003)
Atmospheric growth rate (G_{ATM}) → no demonstrated uncertainties larger than ± 0.3 GtC yr ^{-1, b}				
Ocean sink (S_{OCEAN})				
variability in oceanic circulation ^c	semi-decadal to decadal	global; in particular Southern Ocean	see Sect. 2.4.2	(DeVries et al., 2017)
anthropogenic changes in nutrient supply	multi-decadal trend	global	not included	(Duce et al., 2008)
Land sink (S_{LAND})				
strength of CO ₂ fertilisation	multi-decadal trend	global	see Sect. 2.5	(Wenzel et al., 2016)
response to variability in temperature and rainfall	annual to decadal	global; in particular tropics	see Sect. 2.5	(Cox et al., 2013)
nutrient limitation and supply	multi-decadal trend	global	see Sect. 2.5	(Zaehle et al., 2011)
response to diffuse radiation	annual	global	see Sect. 2.5	(Mercado et al., 2009)

^aAs result of interactions between land-use and climate

^bThe uncertainties in G_{ATM} have been estimated as ± 0.2 GtC yr⁻¹, although the conversion of the growth rate into a global annual flux assuming instantaneous mixing throughout the atmosphere introduces additional errors that have not yet been quantified.

^cCould in part be due to uncertainties in atmospheric forcing (Swart et al., 2014)

1 Figure Captions

2
3 **Figure 1.** Surface average atmospheric CO₂ concentration, deseasonalised (ppm). The 1980-2017
4 monthly data are from NOAA/ESRL (Dlugokencky and Tans, 2017) and are based on an average of
5 direct atmospheric CO₂ measurements from multiple stations in the marine boundary layer
6 (Masarie and Tans, 1995). The 1958-1979 monthly data are from the Scripps Institution of
7 Oceanography, based on an average of direct atmospheric CO₂ measurements from the Mauna
8 Loa and South Pole stations (Keeling et al., 1976). To take into account the difference of mean CO₂
9 between the NOAA/ESRL and the Scripps station networks used here, the Scripps surface average
10 (from two stations) was harmonised to match the NOAA/ESRL surface average (from multiple
11 stations) by adding the mean difference of 0.542 ppm, calculated here from overlapping data
12 during 1980-2012. The mean seasonal cycle is also shown from 1980 (in pink).

13

1
 2 **Figure 2.** Schematic representation of the overall perturbation of the global carbon cycle caused
 3 by anthropogenic activities, averaged globally for the decade 2007-2016. The arrows represent
 4 emission from fossil fuels and industry (E_{FF}); emissions from deforestation and other land-use
 5 change (E_{LUC}); the growth rate in atmospheric CO_2 concentration (G_{ATM}) and the uptake of carbon
 6 by the ‘sinks’ in the ocean (S_{OCEAN}) and land (S_{LAND}) reservoirs. The budget imbalance (B_{IM}) is also
 7 shown. All fluxes are in units of $GtC\ yr^{-1}$, with uncertainties reported as $\pm 1\sigma$ (68% confidence that
 8 the real value lies within the given interval) as described in the text. This figure is an update of one
 9 prepared by the International Geosphere Biosphere Programme for the GCP, using diagrams
 10 created with symbols from the Integration and Application Network, University of Maryland
 11 Center for Environmental Science (ian.umces.edu/symbols/), first presented in Le Quéré (2009).

12

2

Figure 3. Combined components of the global carbon budget illustrated in Fig. 2 as a function of time, for emissions from fossil fuels and industry (E_{FF} ; grey) and emissions from land-use change (E_{LUC} ; brown), as well as their partitioning among the atmosphere (G_{ATM} ; purple), land (S_{LAND} ; green) and oceans (S_{OCEAN} ; dark blue). The partitioning is based on nearly independent estimates from observations (for G_{ATM}) and from process model ensembles constrained by data (for S_{OCEAN} and S_{LAND}), and does not exactly add up to the sum of the emissions, resulting in a budget imbalance which is reflected in the difference between the bottom red line and the sum of the ocean, land and atmosphere. All time series are in GtC yr^{-1} . G_{ATM} and S_{OCEAN} prior to 1959 are based on different methods. E_{FF} are primarily from Boden et al. (2017), with uncertainty of about $\pm 5\%$ ($\pm 1\sigma$); E_{LUC} are from two bookkeeping models (Table 2) with uncertainties of about $\pm 50\%$; G_{ATM} prior to 1959 is from Joos and Spahni (2008) with uncertainties equivalent to about $\pm 0.1\text{--}0.15 \text{ GtC yr}^{-1}$, and from Dlugokencky and Tans (2017) from 1959 with uncertainties of about $\pm 0.2 \text{ GtC yr}^{-1}$; S_{OCEAN} prior to 1959 is averaged from Khatiwala et al. (2013) and DeVries (2014) with uncertainty of about $\pm 30\%$, and from a multi-model mean (Table 5) from 1959 with uncertainties of about $\pm 0.5 \text{ GtC yr}^{-1}$; S_{LAND} is a multi-model mean (Table 5) with uncertainties of about $\pm 0.9 \text{ GtC yr}^{-1}$. See the text for more details of each component and their uncertainties.

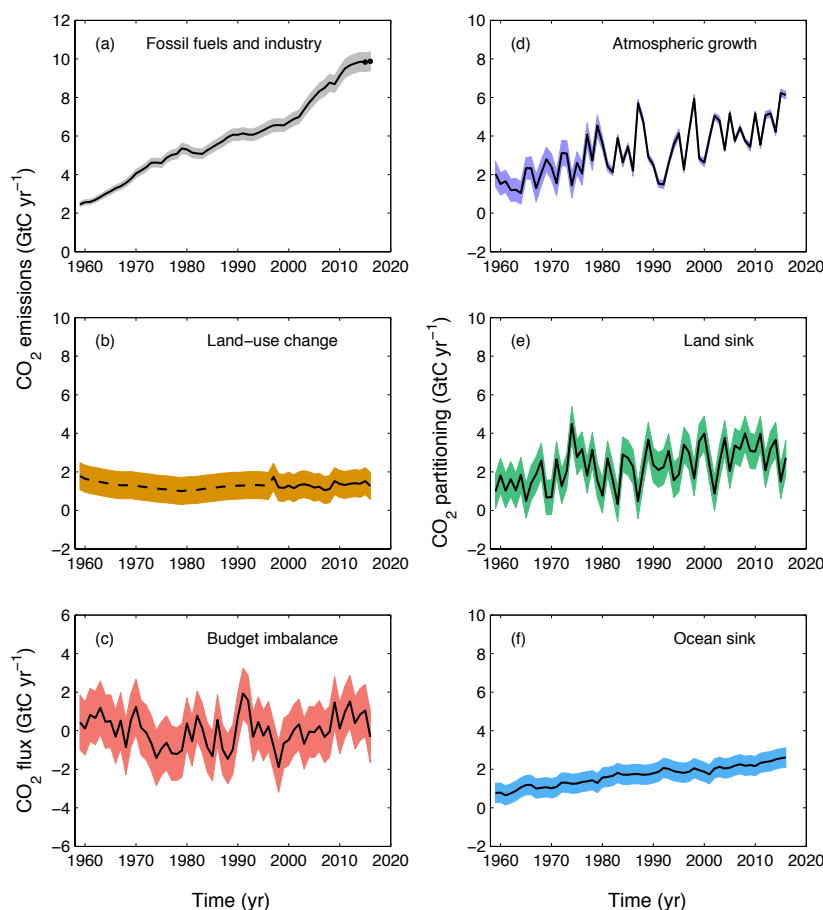

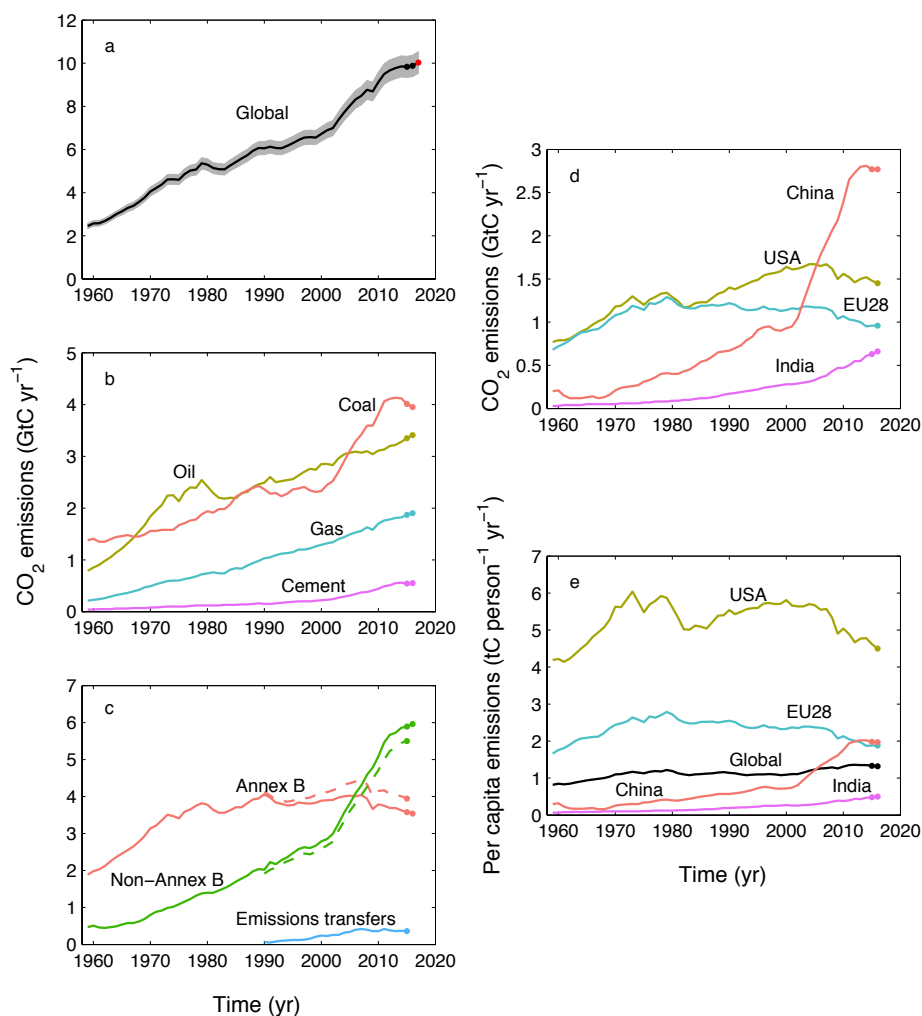

Figure 4. Components of the global carbon budget and their uncertainties as a function of time, presented individually for **(a)** emissions from fossil fuels and industry (E_{FF}), **(b)** emissions from land-use change (E_{LUC}), **(c)** the budget imbalance that is not accounted for by the other terms, **(d)** growth rate in atmospheric CO_2 concentration (G_{ATM}), and **(e)** the land CO_2 sink (S_{LAND} , positive indicates a flux from the atmosphere to the land), **(f)** the ocean CO_2 sink (S_{OCEAN} , positive indicates a flux from the atmosphere to the ocean). All time series are in $GtC\ yr^{-1}$ with the uncertainty bounds representing $\pm 1\sigma$ in shaded colour. Data sources are as in Fig. 3. The black dots in **(a)** show values for 2015 and 2016 that originate from a different data set to the remainder of the data (see text). The dashed line in **(b)** identifies the pre-satellite period before the inclusion of peatland burning.

1
2 **Figure 5.** CO₂ emissions from fossil fuels and industry for **(a)** the globe, including an uncertainty of
3 $\pm 5\%$ (grey shading), the emissions extrapolated using BP energy statistics (black dots) and the
4 emissions projection for year 2017 based on GDP projection (red dot), **(b)** global emissions by fuel
5 type, including coal (salmon), oil (olive), gas (turquoise), and cement (purple), and excluding gas
6 flaring which is small (0.6% in 2013), **(c)** territorial (solid line) and consumption (dashed line)
7 emissions for the countries listed in Annex B of the Kyoto Protocol (salmon lines; mostly advanced
8 economies with emissions limitations) versus non-Annex B countries (green lines); also shown are
9 the emissions transfer from non-Annex B to Annex B countries (light blue line) **(d)** territorial CO₂
10 emissions for the top three country emitters (USA - olive; China - salmon; India - purple) and for

1 the European Union (EU; turquoise for the 28 member states of the EU as of 2012), and **(e)** per-
2 capita emissions for the top three country emitters and the EU (all colours as in panel **(d)**) and the
3 world (black). In **(b-e)**, the dots show the data that were extrapolated from BP energy statistics
4 for 2014 and 2015. All time series are in GtC yr^{-1} except the per-capita emissions **(e)**, which are in
5 tonnes of carbon per person per year ($\text{tC person}^{-1} \text{ yr}^{-1}$). Territorial emissions are primarily from
6 Boden et al. (2017) except national data for the USA and EU28 for 1990-2014, which are reported
7 by the countries to the UNFCCC as detailed in the text; consumption-based emissions are updated
8 from Peters et al. (2011a). See Sect. 2.1.1 for details of the calculations and data sources.

9

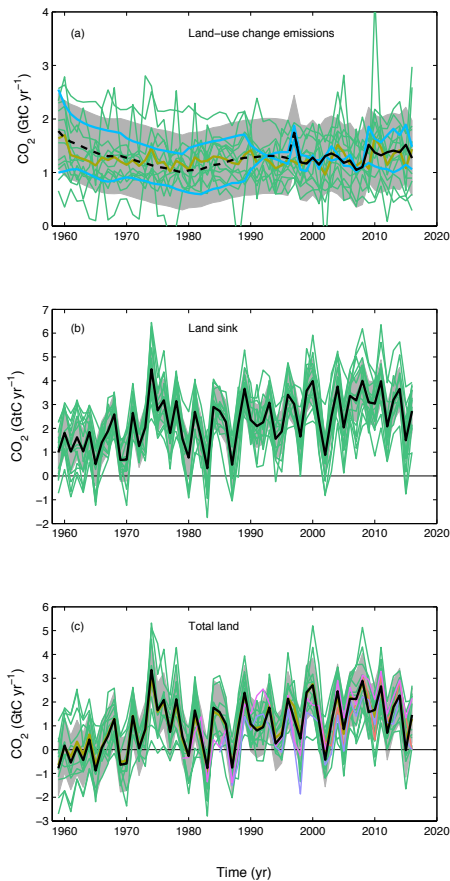

Figure 6. CO₂ exchanges between the atmosphere and the terrestrial biosphere as used in the global carbon budget (black with $\pm 1\sigma$ uncertainty in grey shading), for **(a)** CO₂ emissions from land-use change (E_{LUC}), showing also individually the two bookkeeping models (two blue lines) and the DGVM model results (green) and their multi-model mean (olive). The dashed line identifies the pre-satellite period before the inclusion of peatland burning; **(b)** Land CO₂ sink (S_{LAND}) with individual DGVMs (green); **(c)** Total land CO₂ fluxes (**b minus a**) with individual DGVMs (green) and their multi-model mean (olive), and atmospheric inversions (CAMS in purple, Jena CarboScope in violet, CTE in salmon; see details in Table 5). In **(c)** the inversions were corrected for the preindustrial land sink of CO₂ from river input, by removing a sink of 0.45 GtC yr⁻¹ (Jacobson et al., 2007), but not for the anthropogenic contribution to river fluxes (see Sect. 2.7.2).

1

2

3 **Figure 7.** Comparison of the anthropogenic atmosphere-ocean CO₂ flux showing the budget values
 4 of S_{OCEAN} (black; with $\pm 1\sigma$ uncertainty in grey shading), individual ocean models (blue), and the two
 5 ocean pCO₂-based flux products (Rödenbeck et al. (2014) in salmon and Landschützer et al. (2015)
 6 in purple; see Table 5). Both pCO₂-based flux products were adjusted for the preindustrial ocean
 7 source of CO₂ from river input to the ocean, which is not present in the ocean models, by adding a
 8 sink of 0.45 GtC yr⁻¹ (Jacobson et al., 2007), to make them comparable to S_{OCEAN} . This adjustment
 9 does not take into account the anthropogenic contribution to river fluxes (see Sect. 2.7.2).

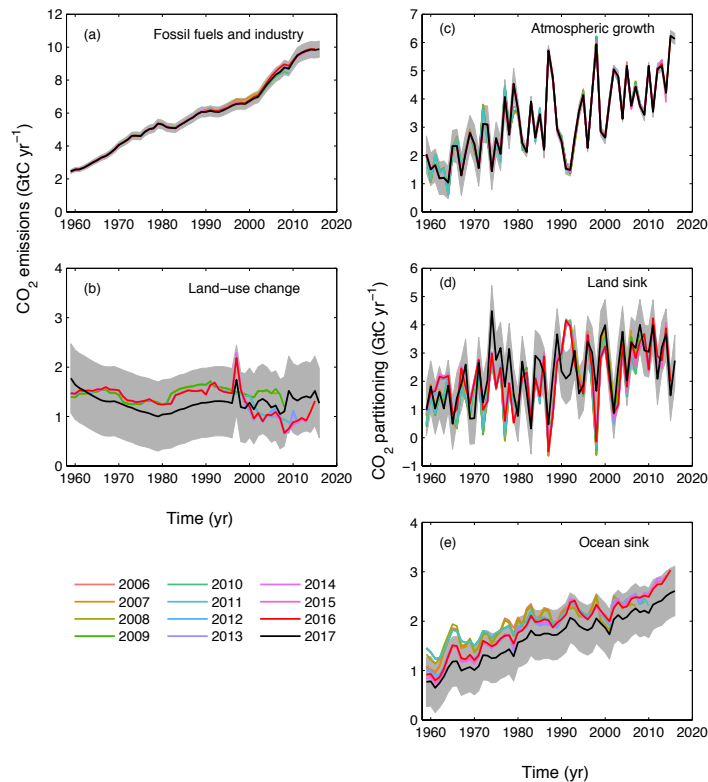

1

2

3 **Figure 8.** CO₂ fluxes between the atmosphere and the surface ($S_{\text{OCEAN}} + S_{\text{LAND}} - E_{\text{LUC}}$) by latitude
 4 bands for the **(a)** North (north of 30°N), **(b)** Tropics (30°S-30°N), and **(c)** South (south of 30°S).
 5 Estimates from the combination of the process models for the land and oceans are shown
 6 (turquoise) with $\pm 1\sigma$ of the model ensemble (in grey). Results from the three atmospheric
 7 inversions are also shown (CAMS in purple, Jena CarboScope in violet, CTE in salmon; references
 8 and version number in Table 5). Where available the uncertainty in the inversions are also shown.
 9 Positive values indicate a flux from the atmosphere to the land and/or ocean.

10

1
 2
 3 **Figure 9.** Comparison of global carbon budget components released annually by GCP since 2006.
 4 CO₂ emissions from **(a)** fossil fuels and industry (E_{FF}), and **(b)** land-use change (E_{LUC}), as well as
 5 their partitioning among **(c)** the atmosphere (G_{ATM}), **(d)** the land (S_{LAND}), and **(e)** the ocean (S_{OCEAN}).
 6 See legend for the corresponding years, and Table 3 for references. The budget year corresponds
 7 to the year when the budget was first released. All values are in GtC yr⁻¹. Grey shading shows the
 8 uncertainty bounds representing $\pm 1\sigma$ of the current global carbon budget.

Table A2 Attribution of fCO₂ measurements for the year 2016 included in SOCAT v5 (Bakker et al., 2016) to inform ocean pCO₂-based flux products.

Vessel	Regions	No. of samples	Principal investigators	Number of data sets
Allure of the Seas	North Atlantic, Tropical Atlantic	71744	Wanninkhof, R.; Pierrot, D.	36
Atlantic Cartier	North Atlantic	44302	Steinhoff, T.; Körtinger, A.; Becker, M.; Wallace, D.	12
Aurora Australis	Southern Ocean	43885	Tilbrook, B.	2
Benguela Stream	North Atlantic, Tropical Atlantic	137902	Schuster, U.; Watson, A.J.	21
Cap Blanche	North Pacific, Tropical Pacific	17913	Cosca, C.; Alin, S.; Feely, R.; Herndon, J.	3
Cap San Lorenzo	North Atlantic, Tropical Atlantic	9126	Lefèvre, N.	3
Colibri	North Atlantic, Tropical Atlantic	27780	Lefèvre, N.	6
Equinox	North Atlantic, Tropical Atlantic	97106	Wanninkhof, R.; Pierrot, D.	35
F.G. Walton Smith	North Atlantic, Tropical Atlantic	43222	Millero, F.; Wanninkhof, R.	16
Finnmaid	North Atlantic	34303	Rehder, G.; Glockzin, M.	3
G.O. Sars	Arctic, North Atlantic	109125	Skjelvan, I.	13
GAKOA (149W 60N)	North Pacific	488	Cross, J.; Mathis, J.; Monacci, N.; Musielewicz, S.; Maenner, S.; Osborne, J.	1
Gordon Gunter	North Atlantic, Tropical Atlantic	59310	Wanninkhof, R.; Pierrot, D.	13
Henry B. Bigelow	North Atlantic	61021	Wanninkhof, R.	13
Investigator	Southern Ocean, Tropical Pacific	108721	Tilbrook, B.	3
Laurence M. Gould	Southern Ocean	26150	Sweeney, C.; Takahashi, T.; Newberger, T.; Sutherland, S.C.; Munro, D.	5
Marion Dufresne	Southern Ocean	3214	Metz, N.; Lo Monaco, C.	1
New Century 2	North Atlantic, North Pacific, Tropical Pacific	25222	Nakaoka, S.	15
Nuka Arctica	North Atlantic	47392	Becker, M.; Olsen, A.; Omar, A.; Johannessen, T.	12
Polarstern	Arctic, North Atlantic, Southern Ocean, Tropical Atlantic	164407	van Heuven, S.; Hoppema, M.	5

Roger Revelle	Indian Ocean, Southern Ocean, Tropical Pacific	93689	Wanninkhof, R.; Pierrot, D.	8
Ronald H. Brown	North Pacific, Tropical Pacific	52267	Wanninkhof, R.; Pierrot, D.	8
S.A. Aguilas II	Southern Ocean	27851	Monteiro, P.M.S.; Joubert, W.R.	
Samiento de Gamboa	North Atlantic, Southern Ocean, Tropical Atlantic	16122	Padin, X.A.	2
Savannah	North Atlantic	2803	Cal, W.-J.; Reimer, J.J.	1
SE Alaska (56N 134W)	North Pacific	271	Cross, J.; Mathis, J.; Monacci, N.; Musielewicz, S.; Maenner, S.; Osborne, J.	1
Skogafoss	North Atlantic	22541	Wanninkhof, R.; Pierrot, D.	4
Tangaroa	Southern Ocean	11897	Currie, K.	7
Thomas G. Thompson	North Pacific, Tropical Pacific	14656	Alin, S.; Cosca, C.; Herndon, J.; Feely, R.	1
Trans Future 5	North Pacific, Tropical Pacific, Southern Ocean	23087	Nakakoka, S.; Nojiri, Y.	21
UNH Gulf Challenger	North Atlantic	2984	Hunt, C.W.	3
